35, Nabha Road, Lahore

PREFACE TO THE FIRST EDITION

Nowadays Statistics has become an important subject and commands its application in almost every science

This book has been written with a view to supply a practical knowledge of the commonly used statistical methods to the beginner although it does not claim to be a detailed treatise on Statistics

The methods have been clearly explained and illustrated with examples

This book covers the syllabuses in Statistics of the various examinations of the Punjab University, such as B A (Hons in Economics) M A B Sc and M Sc (Agriculture) and Commerce Examinations

I hope this book will prove to be useful for

- (1) Statistical workers in general
- (2) Students of the Punjab and other Universities
- (3) Persons preparing for competitive examinations

A good number of Exercises have been given at the end of each Chapter *with answers* for practice

Books given in the Bibliography at the end have been consulted in preparing this book. The Exercises have been mostly taken from various examinations, such as competitive examinations, examinations of the Universities Commerce examinations (Hailey College), class tests etc

* The author will be obliged for suggestions for the improvement of the book

PREFACE TO THE SECOND EDITION

The first edition of Practical Statistics was finished very soon and the demand for the book has been great. The book has been well appreciated by Professors, Government officials, students and the public interested in Statistics.

The second edition is revised and enlarged. The theory (economic as well as mathematical) has been added and the book is brought up to date. The fresh additions are: mathematical theory of interpolation, summary of Bowley Robertson report, list of statistical publications in India, detailed form of Questionnaire, mathematical proofs of theorems on probability and moments and Panjab University Question Papers for 1946. (Questions from other Universities and Competitive examinations are given in the Exercises).

In the Panjab University Statistics forms a subject for (1) Postgraduate certificate in Statistics examination, (2) M. Com. examination and a paper for M.A. (Mathematics), M.A. (Economics), M.Sc. (Agriculture), B. Com., B.A. (Hons. Econ.) and B.A. (Mathematics B Course). This book will be found useful for all the examinations in Statistics.

I am thankful to Professors and students for their kind suggestions.

Definition, Characteristics and Importance of Statistics

The word Statistics is used in the plural as well as in the singular sense. Statistics in the plural are numerical facts systematically collected with some definite object in view in any field of inquiry, whatsoever, of observation or experiment. For example (e.g.) Statistics of, population, births and deaths, height and weight, income and expenditure imports and exports, crimes, morals, rainfall and temperature Railway passengers

Mere figures 60, 62, 65, 68, 70...are not statistics though they are figures, but 60 seers, 62, 65, 68, 70 ..seers, weight of a class of students, will form statistics

The fundamental characteristics are .—

(1) Statistics should be expressed quantitatively. Qualitative words like good, fair, poor, young, healthy, will not be called statistics

(2) Statistics are aggregates that is made up of a number of individuals or cases A single sale, accident or birth will not constitute statistics.

(3) Statistics must be prepared in a systematic manner keeping the given purpose or object in view as clear and definite as possible

(4) Statistics are related to other facts, and should be homogeneous and comparable.

Statistical Method is a technique used to obtain, analyse summarise, compare and present the numerical data (or statistics).

Statistical methods consist of general rules, principles, graphical representation and formulæ applicable to all types of data

Statistics in the singular is a science which investigates the statistical methods and deals with their applications. Statistics deals with (1) populations or aggregates of individuals, (2) Variations in population, (3) Reduction of bulky and incomprehensive data

Like all other sciences, statistics can be classified as (1) pure statistics, (2) applied statistics

Pure statistics or theoretical statistics is mathematical and deals with general theories, formulæ, equations and their derivation

Applied statistics deals with the application of statistical methods to concrete subject matter, such as, measurement of economic, commercial, social, agricultural, industrial, scientific and mental phenomena, measurement of living organisms, study of vital and population movements and actuarial principles

Statistics plays an important part in every walk of life and has proved to be extremely useful in almost every line of scientific and economic inquiry

Economists, businessmen, industrial concerns, bankers, educationists, scientists, astronomers, navigators, insurance companies, railway traffic managements, public bodies, government's departments of public health, meteorology, agriculture, industries, commerce, food, labour, post war reconstruction and planning, are largely benefited by the use of statistics and need statisticians

Limitations

Statistical method which is the only means for handling large masses of numerical data, is limited in its application to data which are reducible to quantitative form. Statistical laws are true on the average and in the long run and do not study the individual constitution of a group. They show approximate tendencies and estimates and they can be used even when experimental methods fail. Statistical methods should be intelligently and carefully used as their misuse may lead to ridiculous and unsatisfactory results. Fallacious conclusions will follow if the data supplied for statistical investigation are incomplete, unreliable and based on prejudiced collection and in such cases science of statistics is not to be blamed at all.

Collection of Statistical Data

The following methods may be conveniently used to have a collection of statistical facts for an inquiry. These collected statistics should be as far as possible, reliable, accurate, clear, without ambiguity, unbiassed, comprehensive and complete for statistical investigations.

The unit of investigation determined should be definite, specific, homogeneous and stable.

The methods of collection may be briefly mentioned as - Method of

- (1) Direct personal investigation or interview method ;
- (2) Indirect investigation ; through correspondence.

(3) Sampling or representative data Sampling may be—

(i) deliberate or purposive, (ii) random, (iii) stratified, Sampling is described in detail later on (Chapter XI)

(4) Questionnaires, (for specimen see Appendix)

(5) Investigation on the basis of government publications, reports of the different departments of governments and states, gazettes, budgets, reports of banks and commercial concerns, research publications, trade and census reports and such other published documents.

Classification and Tabulation

After collection of data, the data should be classified and placed in a tabulated form, as described below

Variates—Any character which can vary in quality or in magnitude is called a variate, thus age, height, occupation, income, colour of the hair and examination marks are variates. Some variates are measurable or quantitative, others are categoric or qualitative. Age and income are quantitative variates, colour of the hair and occupation, are categoric or qualitative, as they cannot be measured numerically.

Classification may be made on either of the four bases :

(1) *Qualitative*—When the basis of distinction rests upon the differences in quality or condition. An analysis of sales by reference to the kind of goods sold involves qualitative distinction.

(2) *Quantitative, i.e., differences being in quantity.* An analysis of sales according to differences in weight, volume or value of the goods involved in each transaction would be quantitative.

(3) *Temporal.*—Involving the time at which the objects in question were measured, or the events in question occurred. An analysis of annual sales by weeks and months will involve temporal classification.

(4) *Spatial or geographical*—Referring to the distribution of items in space or according to location, e.g. annual sales by geographical areas and places.

Classification may be simple and manifold. It may be based on attributes or characteristics in respect of which some are similar, and others dissimilar.

Classification according to one attribute, e.g., deaf not deaf, blind, not blind, in which each class is divided into two sub-classes and no more, is said to be simple. If more than one attribute is noted, classification may be carried further giving rise to several classes and sub-classes. Such a classification will be called manifold classification.

Class intervals and frequencies—Consider the following marks awarded out of 50, obtained by 30 students

3, 5, 8, 15, 25, 30, 16, 7, 35, 40, 49, 40, 30, 15, 14, 21, 23,
22, 25, 27, 29, 32, 15, 1, 8, 9, 11, 14, 42, 43.

The data obtained as a result of observation or experiment in the original form are called 'ungrouped data'. When the data are split into groups or classes, they are called grouped data. The marks given above, form an

grouped data. These marks can be formed into groups or classes by first arranging them in ascending or descending order, as

1, 3, 5, 7, 8, 8, 9, 11, 14, 14, 15, 15, 15, 16, 21, 22, 23, 25, 25, 27, 29, 30, 30, 32, 35, 40, 40, 42, 43, 49.

Such an arrangement in ascending or descending order is called an array

The data can be classified into groups as

<i>Marks</i>	<i>Number of Students,</i>	<i>Marks</i>	<i>Number of Students.</i>
1—5	3	31—35	2
6—10	4	36—40	2
11—15	6	41—45	2
16—20	1	46—50	1
21—25	5		
26—30	4		<hr/> 30

In the first group, 1 and 5 are the class limits, 1 is said to be the lower limit and 5, the upper limit. In each group, 5 marks have been counted, so 5 is said to be the class interval* or the magnitude of the class-interval of the group. The number of students securing grouped marks, against each group, is called the frequency of the class interval or of the group. The frequency of a variate is the number of times it occurs. The data can also be classified with 10 as class interval, counting the upper limit as the next group, as follows

<i>Class intervals</i>	<i>Frequencies.</i>
0—10	7
10—20	7
20—30	7
30—40	4
40—50	5

The total number of frequencies is 30, and the upper limits is counted in the succeeding group

Some people write the classification, to avoid ambiguity, as

0 and under 10	7
10 " " 20	7
20 " " 30	7
30 " " 40	4
40 " " 50	5

The classification is, sometimes, written in the reverse order, taking the last group as first and so on

The following points may be kept in mind while classifying—

1. Class limits must be fixed with reference to the accuracy of the observation.

2. Suitable class intervals should be kept according to the size of the data. It should not be so large as to make the grouped data, look very small, neither so small as to make it look unwieldy. The difference between the greatest and the least value of the data may be divided by the number of conveniently-sized groups to obtain approximately the class interval. As far as possible, attempt should be made to have the class limits as integers and the class interval, itself also a whole number, to facilitate the application of further statistical methods.

3. The class intervals should be uniform as far as possible

4. There should not be indeterminate classes, that is the classes, the intervals of which are not defined, unless unavoidable, e.g.,

Age	Age
Under 5	10—20
5—10	Above 20

Here the first and last classes are indeterminate

5. For a fairly large data, the possible groups can be between 10 and 25

Statistical Series

In order to analyse numerical data, it is necessary to arrange them systematically. An arrangement of the data in a systematic order is called a distribution or series. If the data be grouped according to magnitude or size, the series formed is a frequency distribution, consisting of class intervals and frequencies.

Data grouped according to the time of occurrence, form Time or Historical Series

If Data are grouped according to the geographic location, the resulting series is a spatial distribution

Continuous and discrete series A variate is said to be continuous when it passes from one value to the next by indefinitely small gradations, e.g. height and weight, where we can have differences of small fractions. A variate is said to be discrete (or Integral or discontinuous) when there are gaps between one value and the next, e.g. the number of children in a family, for families differ in size by one or more integers and not by fractions. Continuous variates

will form a continuous series and discrete variates
discrete series

Tabulation—The classified data should be placed in form of Tables with rows and columns. Tabulation is simple and manifold or complex, according as classification is simple and manifold form. A frequency distribution is a frequency table. The following general rules are to be kept in mind for tabulation.

1. First make out a rough draft, but the tables drawn should be accurate, attractive, neat and tidy.
2. Avoid complicated tables. Information of a high degree of complexity should be broken up into sections.
3. The title should constitute a clean, concise and complete description of the material assembled in the table.
4. Headings of the columns and rows should be concise and without any ambiguity.
5. Columns and rows may be numbered to facilitate reference to the table.
6. The table should constitute a unit, self-sufficient and self-explanatory. All explanation necessary for the interpretation of the table should be included as integral part of the table or in the form of foot-notes.
7. The tables should be so constructed as to be easily read and understood, its figures easily compared, and followed without unnecessary waste either of time or thought.

The convenience of the person who needs the table may also be consulted, and the sources of the data should be given.

8 Card system and mechanical system of tabulation may be used when such a machinery is available

Nowadays Machines exist for tabulating as well as calculating purposes

Errors

The divergence between the actual number and the estimate which is made either by approximation or by any other method, is called an Error (it is not a mistake) Errors are absolute, relative, Biassed and unbiased Statistical errors may be due to incomplete and prejudiced information, in adequate sampling and in exact manipulation. If x represents the estimate, y , the true value, then the absolute error e is $y - x$,

and the relative error is $\frac{e}{x}$ [or $\frac{e}{y}$ if the true value is taken]

If a quantity is such that its errors, are all in the same direction, the error is said to be biassed The greater the number of items the greater the error, that is why biassed error is also called cumulative error If a quantity is such that its errors tend to neutralise one another, the error is said to be unbiased or compensating Two important statistical errors namely standard error and probable error are described later on

CHAPTER II

MEASURES OF CENTRAL TENDENCY OR AVERAGES

The fundamental measures of central tendency or averages are—(1) Arithmetic Mean or Arithmetic average or simply Mean, (2) Median, and Quartiles, (3) Mode, (4) Geometric Mean, (5) Harmonic Mean, (6) Weighted average.

In this chapter we shall deal with (1) and (2).

The Arithmetic Mean is calculated as follows —

(i) For ungrouped data, add all the given items and divide the sum by the number of items, e.g. The Mean of Rs. 10, 20 and 30 will be $\frac{10+20+30}{3} = 20$ Rs.

This is the simple Arithmetic average.

(ii) *Direct Method* for grouped data, i.e., when class intervals and frequencies are given. The formula is: Mean $= \frac{\sum fx}{n}$, where $\sum fx$ is the sum of the products of the central or middle or mean values of the groups and their corresponding frequencies, n is the total number of frequencies $= \sum f$. The symbol \sum is used for summation. S is also used in place of \sum (sigma)

*Example.—Weekly Central No. of employees fx
wages (Rs. 5 interval) Values x or frequencies.*

Rs	1—5	125	3	3	9
	6—10	125	8	4	32
	11—15		13	6	78
	16—20		18	1	18
	21—25		23	5	115
	26—30		28	4	112
	31—35		33	2	66
	36—40		38	2	76
	41—45		43	2	86
..	46—50		48	1	48
				30	640

Here $\Sigma fx = 640$, $n = 30$, Mean = $\frac{640}{30} = 21\frac{1}{3}$ Rs

(iii) *Short cut method*—Take any Mean to be called a Provisional Mean, or Assumed Mean or Arbitrary origin, and find the deviations (differences) of the central values from the Provisional Mean. The formula for Arithmetic Mean is then

$$\text{Arithmetic Mean} = \text{Provisional Mean} + \frac{\Sigma f \times d}{n}$$

where d , denotes the deviations of the middle values from the Provisional Mean. Let us work out the above example by taking 13 as the Provisional Mean

x	f	d	$f \times d$	
3	3	-10	-30	
8	4	-5	-20	
13	6	0	0	Arithmetic Mean
18	1	5	5	$= 13 + \frac{240}{30} = 21\frac{1}{3}$
23	5	10	50	This gives the average wage
28	4	15	60	The same result as by
33	2	20	40	direct method
38	2	25	50	
43	2	30	60	
48	1	35	35	
<hr/>			<hr/>	
30			250	

Any Provisional Mean may be taken, but as a convention, the middle value corresponding to the maximum frequency in the given distribution is to be taken as a Provisional Mean. The short cut method proves more useful in case of a large data, or if there are decimals, than

the direct method. For the sake of convenience, to avoid heavy multiplication, the magnitude of the class interval may be taken common out of the deviations. In the above example 5 can be taken out common in column d , and then multiplied at the end by $\sum f \times d$, so formed

Advantages of Arithmetic Mean—(1) The Arithmetic average is the most commonly used average. (2) It is easily calculated and understood and is the most generally recognised type of average. (3) It utilises all the data in the groups.

Disadvantage—Its value may be greatly distorted by the extreme values and, therefore, sometimes it may not be typical.

Median, Quartiles, Deciles and Percentiles—Consider an ungrouped data arranged in ascending or descending order, i.e. an arrayed data. The middle item of the array is called the Median. It is the central item which has as many items preceding as succeeding it. When the number of items is odd, the median can be easily located. e.g. If there are eleven items, the median will be represented by the 6th item (five items preceding and five, following it). If n is the number of items, the median will be $\left(\frac{n+1}{2}\right)$ th item. When the number of items is even, there will be two central values $\left(\frac{n}{2}\right)$ -th and $\left(\frac{n}{2} + 1\right)$ th, item. Either of them can be taken as Median and the Mean of these two central values may be taken as the Median Value.

For grouped data, i.e., for a frequency distribution, the Median is calculated with the help of the formula

Median $= l + \frac{i}{f} \left(\frac{n}{2} - c \right)$ Where n is the total number of frequencies, $\frac{n}{2}$ the median number which will lie in a group whose lower limit is l , i is the class interval of the Median group i.e., in which the median lies, and f its corresponding frequency, c denotes the cumulative frequency of the group preceding the Median group.

Example.—Let us work the median for the previous example.

Groups.	Frequencies	Cumulative Frequencies.
1—5	3	3
6—10	4	7 i.e. (3+4)
11—15	6	13 i.e. (7+6)
16—20	1	14 i.e. (13+1)
21—25	5	19
26—30	4	23
31—35	2	25
36—40	2	27
41—45	2	29
46—50	1	30
<hr/>		
30		

The cumulative frequencies are 3, 7, (3+4), 13 (3+4+6), 14, 19, 23, 25, 27, 29 and 30. $\frac{n}{2} = \frac{30}{2} = 15$ lies in the group 21—25. This is the Median group, whose lower limit is 21, the given frequency corresponding to this group is 5 and i is also 5. Therefore, Median $= 21 + \frac{5}{5} (15 - 14) = 22$.

For the Median number $\frac{n}{2}$ is used for continuous as well as for discrete series. But for discrete series $\frac{n+1}{2}$ can be used when n is odd

Advantages and Disadvantages — The median is typical, when the central values of the series are closely grouped, and the array consists of terms quite close to each other. It can be located by inspection and is not distorted by extremes or unusual terms. For the data of the type.

Frequencies

Below 5	—	
5—10	..	Median is a better average than Arithmetic Mean
10—15	...	
Above 15	—	

Median is not so familiar an average as the Arithmetic Mean.

In locating the Median, the items have to be arrayed which is not done in the case of Arithmetic average.

Quartiles, Deciles and Percentiles — Just as the median divides the distribution into two parts, the Quartiles divide it into four parts, Deciles into ten parts and the Percentiles into one hundred parts. To determine the values of these measures

the same process is used as for median except that we use $\frac{n}{4}$

for first quartile Q_1 for second quartile, $\frac{2n}{4}$, and for third quartile Q_3 , $\frac{3n}{4}$. Thus $Q_1 = l + \frac{f}{f} \left(\frac{n}{4} - c \right)$ $Q_3 = l + \frac{f}{f} \left(\frac{3n}{4} - c \right)$

For discrete series when n is odd $n+1$ can be used in place of n

For deciles we can use $\frac{n}{10}$ for first decile, $\frac{2n}{10}$ for second and so on

For Percentiles we may use $\frac{n}{100}$ for first Percentile $\frac{2n}{100}$ for second and so on and proceed exactly as for median

Besides these measures of comparison we have also Quintiles and Octiles which divide the distribution into five and eight parts respectively. The rest of the formulae and process is the same as for Median for all these measures

In the above example $Q_1 = 11 + \frac{1}{8} (24 - 7) = 11\frac{7}{8}$, as $\frac{3}{8}$ lies in the group 11—15

Exercise I

1 How will you proceed to conduct an economic inquiry of your own native place?

2 Prepare Questionnaires for (1) your own college (2) big factory or firm (3) well known Bank

3 Draw Table for the data given at the end of the Exercise I

4 Draw Tables to show the distribution of population of your Province by (1) age, sex and literacy (2) Sex and occupations

5 Form frequency table of the following taking class intervals as 2, 2.5 and 3 respectively

Rupees 1, 7, 4, 28, 35, 42, 35, 72, 5, 34, 15, 25, 172, 193, 19, 27, 264, 291, 302, 146, 23, 15, 2913, 1045, 137, 149, 27, 35, 193, 209, 175, 128, 19, 39

6. Find the Arithmetic Mean and Median of the following observations $22, 24, 20, 25, 21, 19, 23, 22, 20, 22, 23, 25, 21, 24, 26, 22, 24, 23, 22, 22, 21, 23$.

Ans Mean 21.96 and Median 22

7. Form a frequency distribution of the following data giving the index numbers of 60 commodities in a certain year and find the value of the Mean and the Median $76, 78, 81, 85, 86, 87, 89, 90, 91, 94, 95, 96, 96, 98, 97, 99, 99, 102, 100, 10, 104, 101, 107, 104, 101, 104, 105, 105, 106, 107, 105, 103, 103, 109, 109, 110, 117, 111, 112, 113, 113, 114, 114, 115, 116, 116, 117, 117, 118, 119, 120, 121, 122, 123, 134, 125, 128, 119, 134$

(M.A. 1942 Punjab University)

(Ans 106.83) 107.22

8. Given, Height in inches x 73, 77, 71, 70,
Men (f) 2 4 6 10
69 64, 67, 66, 65
11 5 4 1

Calculate the mean height.

Ans 69.18

9. Given Variate, x 19, 15, 17, 16, 15,
Frequency 1 2 4 8 11 10
14, 13, 11, 11
7 4 2 1

Find the Mean variate (1) by taking 11 as the origin (2) 15 as Zero (i.e. as Pro Mean) and verify by the direct method

Ans 15.54

10. Given the following frequency distribution, calculate the Arithmetic Mean

Monthly Wages	Workers	Monthly Wages	Workers
Rs Rs		Rs Rs	
12.5—17.5	2	37.5—42.5	4
17.5—22.5	22	42.5—47.5	6
22.5—27.5	14	47.5—52.5	1
27.5—32.5	14	52.5—57.5	1
32.5—37.5	3		

(M Sc Agriculture 1943)

Ans Rs 27.85

✓ 11 (a) Find the median quartiles, 5th decile and 56th percentile for the following distribution

Class Intervals	Frequency	Class Intervals	Frequency
Rs		Rs	
1—2.99	6	11—12.99	16
3—4.99	53	13—14.99	4
5—6.99	80	15—16.99	4
7—8.99	56		
9—10.99	21	Total	245

Hint — In such decimal classes consider class interval, a whole number, in this case the interval is 2 and groups as class interval 2

1—3

3—5 for computation

Ans 5.49 $Q_1 = 5.05$, $Q_3 = 8.4$ $D_4 = 8.86$ and $P_{56} = 6.8$

(6) Given

Rs		Rs	
4—7 999	4	28—31 999	22
8—11 999	16	32—35 999	10
12—15 999	46	36—39 999	2
16—19 999	68	40—43 999	2
20—23 999	58	44—47 999	0
24—27 999	32	48—51 999	1

Calculate the Arithmetic Average

Ans 20 6

√12 Calculate the median, the lower Quartile and the upper Quartile for the following frequency distribution of the number of marks obtained by 49 students in a class —

Marks obtained	No of Students	Marks obtained	No of Students
5—10	5	25—30	5
10—15	6	30—35	4
15—20	15	35—40	2
20—25	10	40—45	2

(Punjab University B A Hons 1942)

Ans 19 6 15 41, 25 75

√13 Find the median and the first Quartile

Amount of wages	Number of workers so receiving such Rate of wages
Not exceeding 10 shillings	50
Over 10s but not exceeding 12s	10
Over 12s „ „ 14s.	60
Over 14s „ „ 16s	81
Total	261

Hint — Take the median number as $\frac{261+1}{2} = 131$

and for $Q_1 = \frac{261+1}{4}$.

Ans 12s 4d pence $Q_1 = 10s. 5d.$

14 Calculate the median

(a) x Rs. 10, 8, 6, 4, 2.

frequency 1, 4, 6, 4, 1

(b) x Rs. 20, 40, 60, 80

f 10, 50, 30, 10.

(c) x 10, 12, 14, 16, 18, 24.

f 2, 5, 6, 4, 2, 1

(d) x 3, 5, 7, 9.

f 200, 400, 300, 100.

Hint. — First of all put x into class intervals, so as to have x as the middle values and then proceed in the ordinary way.

	γ	x
For (d) Class intervals are	2-4	3
	4-6	5
	6-8	7
	8-10	9

Ans. (a) 6, (b) 46, (c) 14, (d) $5\frac{7}{2}$

15. Find the Median and Quartiles for the following frequency distribution.

	<i>f</i>
Rs. 12, 8 ans.—Rs. 17, 8 ans.	4
" " " — " " " " "	44

	15	20	12	10
	44—48,	48—52,	52—56,	56—60
	6	4	1	

Ans. 33.81

(Hyderabad University B A. 19)

28. The table shows the age distribution of married males according to sample census of 1941 in the Baroda taluka

Age	0—5,	5—10,	10—15,	15—20,	20—25,
Number of married females	3	31	410	1809	2446
	25—30,	30—35,	35—40,	40—45	
	2223	1723	1292	963	
	45—50,	50—55,	55—60,	60—65,	
	762	531	317	156	
	65—70,	70—75			
	59	37			

Calculate the median age of married females and also the two quartiles

Ans. 28.78, 21.91, 38.58.

(Indian Audit & Accountants Service Exam, 1942).

29 Calculate the Quartiles for the following frequency distribution of weights of a certain class of people:—

Weights in pounds 100—105, 105—110

Number of persons 5, 10, 15, 65, 40, 32

170—175.
44, 35, 40, 29, 30, 25, 15, 10, 8

Ans $120\frac{23}{32}$, $147\frac{93}{116}$

(Indian Audit & Acctt. Exam 1945)

30 Compile the statistical data contained in the following paragraph in tabular form —

The United States Bureau of Foreign and Domestic Commerce presented, in the December 1937 "Monthly

Summary of Foreign Commerce ' data of exports of United States merchandise and of imports for consumption (not including imports for purposes of re export), segregated into "economic classes and for various years. Comparing 1936 and 1937, the total value of exports was \$2 418,969,000 in 1936 and \$3,294,916,000 in 1937, while the total value of imports for consumption was \$2 423,977,000 in 1936 and \$3,012,487 000 in 1937. Crude materials exported in 1936 amounted to \$668,168,000, or 27.6 per cent of the total value of exports for that year, and in 1937 were \$721,871 000 or 21.9 per cent of that year's total. Imports of crude materials amounted to \$732,965,000 in 1936 and \$973 535,000 in 1937, or respectively 30.2 per cent and 32.3 per cent of total imports for consumption in the two years. Crude foodstuffs exported in 1936 were valued at \$58,144,000 which was 2.4 per cent of total exports for that years, and \$101,742 000, or 3.1 per cent of the total in 1937. Imports of crude foodstuffs for consumption were \$348,682,000 or 14.4 per cent of the total value of imports for consumption in 1936, and \$413,345,000 or 13.7 per cent of the total in 1937. Manufactured foodstuffs exported in 1936 came to \$143 798 000 or 5.9 per cent of the year's total and in 1937 were \$177,451,000 or 5.4 per cent of the total. Imports of manufactured foodstuffs for consumption amounted to \$385,240,000 or 15.9 per cent of the total imports in 1936 and \$440,103,000 or 14.6 per cent of the total in 1937. Semi manufactures exported in 1936 were valued at \$394,760 000 or 16.3 per cent of the total, in 1937 they were \$577 254,000 or 20.6 per cent. of the years exports. Imports of semi-manufactures for consumption totalled

\$490,238,000 or 20.2 per cent of all imports for consumption in 1936 and \$634,181,000 or 21.1 per cent of the total in 1937. Finished manufactures worth \$1,154,099,000 of 47.7 per cent of the total for that year were exported in 1936, and \$1,616,598,000 worth, or 49.1 per cent of the total, in 1937. Of finished manufactures imported for consumption \$465,852,000 worth or 19.2 per cent of all imports for consumption, came in during 1936 and \$551,323,000, or 18.3 per cent of the total were received in 1937.

(B. A. Hons 1944)

CHAPTER III

MODE, WEIGHTED AVERAGE, GEOMETRIC AND HARMONIC MEANS

Mode

Mode is the predominant item in a series, it is the size of the variable that occurs frequently or the position of the greatest density.

Local inquiries into wages frequently require the 'current' wage or the 'usual' wage. This wage should be considered as Modal wage.

Inquiries regarding modal wages, rents, price etc., are frequently answered off hand by experienced businessmen whilst enquiries as to Average quantities, would involve a considerable amount of labour. Mode is also called Norm.

Meteorological forecasts are based on the use of the mode. In studying output, Mode proves of great advantage.

To locate the position of mode, the following formulae may be used. First Group the data, notice the maximum frequency and apply

$$(1) \text{ Mode} = l + \frac{f_m - f_1}{(f_m - f_1) + (f_m - f_2)} \times i.$$

Where l is the lower limit of the modal group, that is the group having the greatest frequency ; being its magnitude.

f_m is the maximum frequency, f_1 , the frequency of the group preceding the modal group and f_2 of the group following the modal group

$$(2) \text{ Mode} = l + \frac{f_2}{f_1 + f_2} \times i$$

This is more handy than (1) for calculation, but (1) gives more precise position

$$(3) \text{ Mode} = 3 \text{ Median} - 2 \text{ Arithmetic mean.}$$

This formula is quite general for the calculation of mode. In case of frequency distribution, where two or more equal maximum frequencies occur, this formula is to be used.

Example 1.—	Marks out of 10	Number of Students.
	2—4	20
	4—6	40
	5—8	30
	8—10	10

The group (4—6) contains the maximum frequency 40 so it is a modal group with 2 as its magnitude, 10 being the maximum or modal frequency

$$\text{by (1) Mode} = 4 + \frac{40 - 20}{20 + 10} \times 2 = 5\frac{1}{3} = 5.33$$

$$(2) \text{ Mode} = 4 + \frac{30}{20 + 30} \times 2 = 5\frac{1}{5} = 5.2$$

$$\text{✓ (3) Mean is } 5\frac{2}{3}, \text{ Median } 5\frac{1}{2}$$

$$\therefore \text{ Mode} = 5.2 - \frac{1}{5} = 5\frac{1}{5} = 5.2$$

Symmetrical distribution — If in a series, the mean, median and the mode are the same, the distribution is said to be symmetrical otherwise non-symmetrical

Advantages and disadvantages of Mode —

1. Mode is easily understood and like median it may be spotted by inspection, an advantage which the Arithmetic Mean does not enjoy.

2. Like the median and mean, it can be calculated when data fall into groups

3. It is the average of position and proves useful for non-quantitative data also

Disadvantage — It is frequently ill defined and becomes difficult to locate exactly by the formulae. Its significance is limited when a large number of values is not available.

Weighted Average

The Arithmetic average gives equal importance to all the items in a series and it cannot be advantageously used where it is necessary to give unequal importance to different items. In such cases weighted average has to be used

Due importance is given to each item by weighting it.

The object of weighting is to give proper importance to different data. Weights are assigned to each item in proportion to its importance in influencing the final result and each item is multiplied by its weight or by the number of persons or things connected with it, and the products added up. The total sum of the products is divided by the sum of weights (or by the number of persons or things connected with it) and the result is the *Weighted Average*. Weighting may be essential when the series is small, very large series, weighted average and Arithmetic average tend to be the same. Weights are estimates of relative importance.

Example 2—

Description of workers	FACTORY A.			FACTORY B.		
	No of	Daily wage		No of	Daily wa,	
	em- ployees	per employee		em- ployees	per emplo:	
		Rs	a. p.		Rs	a.
(a)	200	3	8 0	320	2	4
(b)	20	1	8 0	40	1	4
(c)	250	2	8 0	300	4	0
(d)	150	5	0 0	200	5	0
	620			860		

Simple Arithmetic Average for

$$\text{Factory A} = \text{Rs. } \frac{3 \cdot 5 + 1 \cdot 5 + 2 \cdot 5 + 5}{4} = \text{Rs. } 3 \cdot 125 \text{ which}$$

the same for B also, so no comparison is possible.

Weighted average for Factory B

$$= \frac{(2.25 \times 320) + (1.25 \times 40) + (4 \times 300) + (200 \times 5)}{320 + 40 + 300 + 200}$$

$$= 3.453 \quad \text{For factory A, weighted average}$$

$$= \frac{3.5 \times 200 + 1.5 \times 20 + 250 \times 2.5 + 5 \times 150}{200 + 20 + 250 + 150} = 3.395$$

as there is a marked difference in average wages

Geometric and Harmonic Means

Geometric mean is the n th root of the product of n items.

If a, b, c, \dots, z are n items then $G = (a \cdot b \cdot c \cdot d \cdot \dots \cdot z)^{\frac{1}{n}}$

Thus the G mean of 4 and 9 is $(4 \times 9)^{\frac{1}{2}} = 6$ G. M. of

5, 8 and 25 is $(5 \cdot 8 \cdot 25)^{\frac{1}{3}} = 10$ G. M. can be easily calcu

lated with the help of logarithms, i.e., the logarithms (logs) of the items are averaged and the anti logarithm (anti log) of this average will give the G. M. The logs can be looked up easily from the Table of Logarithms

Example 3—To find G. mean of (a) 20, 5 and 10. Using log table, $\log G = \frac{1}{3} (\log 20 + \log 5 + \log 10)$

$$= \frac{1}{3} (1.3010 + .6990 + 1.000) = 1$$

$$\therefore G = 10$$

(b) To find G. M. of the grouped data

	x	f	$\log x$	$f \times \log x$
2—4	3	20	.4771	9.542
4—6	5	40	.6990	27.96
6—8	7	30	.8451	25.353
8—10	9	10	.9542	9.542
		<hr/> 100		<hr/> 72.397

$$\log G = \frac{\sum (f \log x)}{\sum f} = \frac{72.397}{100} = .72397 \quad \therefore G = 5.297$$

Harmonic Mean is the reciprocal of the average of the reciprocals of the items in a series. Harmonic mean of n items will be

$$\frac{n}{\frac{1}{a} + \frac{1}{b} + \dots + \frac{1}{z}}$$

Example 4—To find Harmonic Mean for ungrouped as well as grouped data

(a) To find H M of 5 and 25. There are two items and, therefore $n=2$

$$\text{and H M} = \frac{2}{\frac{1}{5} + \frac{1}{25}} = \frac{2}{\frac{2+1}{25}} = 33$$

(b) x	Reciprocals $\frac{1}{x}$	Frequency f	$f \times \frac{1}{x}$
3	$\frac{1}{3} = 333$	20	6.66
5	$\frac{1}{5} = 2$	40	8
7	$\frac{1}{7} = 143$	30	4.29
9	$\frac{1}{9} = 111$	10	1.11
		100	20.06

$$\text{Harmonic Mean} = \frac{100}{20.06} = 4.98$$

$$\text{In general H M} = \frac{\Sigma f}{\Sigma \left(f \times \frac{1}{x} \right)}$$

Reciprocals can also be taken from the table

Advantages and disadvantages of these Means—

Harmonic Mean is less than the Geometric Mean which is less than Arithmetic Mean. If in the data, Arithmetic Mean fails to give a satisfactory average, or the average being too big in comparison with data, then Geometric Mean is to be used and if that also is unsatisfactory, then Harmonic, but Harmonic is not much used in practice.

If two or more series are to be compared and Arithmetic Mean comes out to be the same then Geometric Mean can be used

Geometric Mean is less affected by extremes. It is particularly useful in the Construction of Index Numbers

Geometric Mean cannot be determined where there are negative values in the series or where one of the items is zero and moreover it involves lot of calculations

Exercise II

I—Find the Mode for the data in Q 14, Exercise I. Are these symmetrical distributions?

Ans Using formula (I) (a) 6, (b) 43.3,
(c) $13\frac{1}{2}$, (d) $5\frac{1}{2}$ (a) is symmetrical.

II—Calculate the G Mean and H M for Q 14, Ex I (a and b)

Ans (a) 5.615, 5.161, (b) 45.11, 42.15

III—(a) Find the Geometric Mean of 50, 80, 200 and 100 and compare with the Arithmetic and Harmonic Mean

Ans 94.57 107 $\frac{1}{2}$ 84.21.

(b) Find the Mode of

0—4	10
4—8	20
8—12	30
12—16	30

Ans $10\frac{8}{9}$

IV—Find the Mean, median and Mode of—

Class intervals,	6.5—7.5	7.5—8.5	8.5—9.5,
Frequencies	5	12	25

9.5—10.5,	10.5—11.5	11.5—12.5,	12.5—13.5
48	32	6	1

Ans 9.87, 9.98 10.2

V — Determine the Mode in Q IV by using formula (2).

Ans 10 06.

VI — Compute the modal wage for the following frequency distribution of wages —

Central wage Rs 15 20, 25, 30, 35, 40, 45, 50, 55

Wage earners 2, 22, 19, 14, 3, 4 6, 1 1.

Ans Classify the wages as 12 5—17 5 etc

Apply formula (1) 21 85.

VII — Table showing the frequency with which profits are made What is the Mode ?

Frequency

Exceeding Rs	3 000 and not exceeding	4,000	3
"	"	4,000	7
"	"	5,000	22
"	"	6 000	60
"	"	7,000	85
"	"	8,000	32

Ans using (2) Rs 7347 82,

VIII — The annual incomes of fifteen families are given below in Rupees 80, 2,500 90, 1,200, 1,450, 7,200, 120, 1,060, 150, 480, 360, 96, 200, 520, 60 calculate the Arithmetic Average, Geometric Mean and the Harmonic Mean

(P U. M A. 1940). Ans 1037 7, 377 3, 186

IX — The following is the distribution of wages per thousand employs in a certain factory —

Daily wages in annas	2	4	6	8	10	12	14	16	18	20	22
	3	5	7	9	11	13					
Number of employees	8	13	43	102	175	220	204	139	69	25	6

Calculate the modal and median wages and explain why there is a difference between the two

(E A. (Hons.) 1943) Ans $x_{\frac{29}{51}}$, $x_{\frac{27}{55}}$

↓ X.—The following marks have been obtained in three papers of Statistics in an Examination by 12 students. In which paper is the general level of the knowledge of the students highest? Give reasons,

A 36, 56, 41, 46, 54, 59, 55, 51, 62, 44, 37, 59.

B 58, 54, 21, 51, 59, 46, 65, 31, 68, 41, 70, 36

C 65, 55, 26, 40, 30, 74, 45, 29, 85, 32, 80, 39.

Ans Paper A

↓ XI—Calculate the Average for

Items	Expenditure	Weight
Food	29	7.5
Rent	54	2
Clothing	97.5	1.5
Fuel and light	75	1
Other items	75	5

Ans, 46.74.

↓ XII—The following table gives the number of employees and their monthly earnings in two factories of a particular city:—

Description of workmen	A		B	
	No of employees	Monthly earnings	No. of employees.	Monthly earnings
		Rs.		Rs.
(a) ..	4	800	1	750
(b) ..	22	45	8	125
(c) ..	20	100	10	50
(d) ..	30	30	20	40
(e) ..	80	35	30	45
(f) ..	300	15	100	15

Compare and find the weighted average.

Ans 31.5 and 34.9.

XIII.—Calculate the geometric and harmonic means weights in maunds

250, 12, 45, 119.5, 30, 42, 35.4, 75.

Ans 39.8, 19

XIV.—Determine the mode and Geometric Mean :
Questions 23—27 (Exercise I) and compare the averages

CHAPTER IV

DIAGRAMS AND GRAPHS

The statistical data can be presented in the form of diagrams, charts, graphs and pictures, so as to permit immediate grasp of the significance attached to it. The method of diagrammatic representation is used for the purpose of comparisons. In business, it is necessary to call for data relating to Sales, Purchases, Stock Expenses, Cash Balance, etc., and if these are presented to the business man in a graphic form in such a way that comparison could be made between two or more periods, or two or more related items, it would be easier to understand, than analyse the tabular statements and also save a lot of time. Great care should be taken in the choice of suitable diagrams depicting a concise picture of the statistical data. The size of the diagram should be just sufficient to enable the eye to perceive the features of the figures which it claims to stand for. The diagrams should be neatly and accurately drawn with the help of instruments and they should be attractive and complete as far as possible. To bring out the distinction clearly, various kinds of dottings, lines, pencils of colours, crossing or colouring or some other methods may be used.

The following types of diagrams, charts and graphs are commonly used

(1) Simple Bar Diagrams, (2) Subdivided Bars or Compound Bar Diagrams and Percentage Bar Charts, (3) Rectangular Diagrams, (4) Squares Cubes and Circular Diagrams (5) Pictograms, (6) Historigrams, (7) Logarithmic or Ratio Charts (8) Graphs of Frequency Distributions

(1) Bars or thick lines of uniform breadth and with uniform space in between, are drawn to represent the given items, the magnitude being represented along the vertical side of the bar on a convenient scale and the items arranged in ascending or descending order of magnitude

(2) If a magnitude is capable of being broken into component parts or if there are independent quantities which form the subdivisions of the total, in either of these cases, bars may be subdivided into the ratio of the various components to show the relationship of the parts to the whole. If the imports and exports of a country are given, the sum of the two, the total foreign trade, will be represented by the height of the bar, imports and exports will be the subdivisions. Total population of a country may be represented by the height of the bar and the males and females will be the subdivisions (See also Exercise III, 2)

If the subdivisions are more than two, the subdivisions may be reduced to percentage of the whole. The height of the bar will represent 100 and the other components in percentages may be represented on the bar. This will be a percentage Bar diagram

(3) Bar diagrams explained above, are supposed to have no breadth at all, but Rectangular diagrams have breadth as well as height

The area of the rectangle will represent a magnitude. Rectangles may be used when two or more quantities are to be compared and each is sub-divided into several components. For instance, when it is desired to show differences in expenditure, on the same item, in two family budgets with different incomes, rectangles can be used with incomes as the breadth of the rectangles and 100 as the height of the rectangles. The several items of expenditure may be reduced as percentages and represented on the rectangles. A uniform scale is to be used for the rectangles. e.g. See Exercise III, 6),

(4) *Squares, Cubes and circular diagrams*—When quantities bearing large ratios such as 1 : 100 or near about, are to be compared, bar diagrams do not serve the purpose as a suitable scale cannot be selected. In such cases, squares are used

Take the square roots of the given items (arranged in ascending or descending order) and with these square roots as the sides construct squares with a convenient scale, keeping a uniform space in between the squares. (e.g., see Exercise III, 7). If the ratios in quantities are 1 : 1000 or near about, cubes are drawn with cube roots as sides

As it may take more time to construct squares, circles can be used in place of squares. With square roots of the items draw circles of all the items. T

centres should be placed in a horizontal line. Circles are also called **Pie Diagrams**.

Sectors of the circle can also be used for comparing several items, the subdivisions being represented as follows —

Suppose we are given the population of several countries. Let the circle represent the total of the populations. The whole circle covers 360 degrees, that is (i.e.) the whole population = 360. Express the populations of other countries in degrees and draw these angles in the circle. The sectors so formed will represent the different populations. If the total population is 120 millions and of one country is 10 millions, then the angle of the country is $\frac{360}{120} \times 10 = 30$. The sector containing 30° will represent the population of the country.

(5) *Pictograms* — Numerical data are generally given a beautiful and attractive summary representation by means of appropriate maps or cartograms, and pictures or pictograms. In drawing pictures it should be borne in mind that the proportions to which the natural objects are reduced should not be disturbed. Maps with different colours may be used to visualise the distribution of population in an impressive manner. For ocular comparison of figures dotted maps are widely used. Density of population, the average yield per acre of crops in various parts of a country and many other similar statistics may be indicated by means of dots in a map.

(6) *Historigrams* — Diagrams pertaining to historical or time series are said to be historigrams. The years

HISTORIGRAMS

Purchases

— 50 —

Rupees in Lacs

or months as the given time may be are plotted along the horizontal line (called the axis of x) on the graph paper the data corresponding to the periods are plotted along the vertical line (called the axis of y). This plotted points are joined by straight lines. This will be a Histogram drawn on a convenient scale. The point where the axis of x and the axis of y meet is called the origin which is zero for vertical values. If there are two or more series on the same periods they can be plotted on a convenient scale with origin as zero for vertical values and thus their fluctuations can be compared. Commercial data such as Records of sales Purchases and Sales Gross Profits and Expenses Turnover and Net Profit can thus be represented graphically. Some distinction may be made when there are two or more time series.

Example—To draw the Histograms for the data showing purchase and sale for 12 months given in Lacs of Rupees

	January	Feb	March	April	May	June
Purchases	40	42	48	52	54	56
Sale	50	60	60	65	80	74
	July	August	Sept	Oct	Nov	December
Purchases	61	64	66	66	80	86
Sales	72	70	65	60	64	70

The months are shown along the horizontal axis and the rupees in lacs along the Vertical axis in the diagram.

(7) *Logarithmic or Ratio graphs*—So far we have been dealing with data drawn on the natural scale the

equal vertical distances represent equal absolute movements. The ratio scale is employed as an alternative to the natural scale, whenever it is desired to study relative movements. An absolute series may be converted into a ratio series by plotting either (1) the logarithms of the actual figures of the given items, or (2) the figures themselves on a semi-logarithmic paper. Method (1) is generally used as the logarithmic paper is not easily available. The logarithms can be looked from the tables and then plotted. The plotted points may be joined by means of straight lines to obtain a Logarithmic Graph (or Ratio Chart) or by a free hand curve when possible. Ratio scale cannot show zero and negative values which the natural scale can. A constant rate of change, growth or decline is indicated by a straight line on a logarithmic graph. The stability or instability of prices or any other such variable can be brought out by the logarithmic graph.

Example — To draw a population graph from the following data on a ratio scale for the population of India in lakhs

Years	1881,	1891,	1901,	1911,	1921,	1931
Population	2539,	2873,	2944,	3150,	3189,	3530

The logarithms of the figures in population, are,
8.4048, 8.4584, 8.4689, 8.4983, 8.5037, 8.5478

Plotting these as in histograms, we get the required graph (approximate value in decimals may be taken while plotting).

example given above, we are given the population during the years 1881—1931. If we are required to estimate the population for any intervening year say 1926, not given in the data, interpolation has to be used as follows. Mark the year (say 1926) along the axis of x , and at this point erect a perpendicular (called Ordinate) cutting the graph at a certain point. The length of this Ordinate will indicate an estimate of the population for 1926. Looking its value from Logarithmic tables, we shall have the estimate of the population. Extrapolation can also be done graphically if the data happen to be organic in character. It means, finding the value for the year beyond the years given in the data, i.e., after 1931 in this example. Plot the year (say 1941) along the x axis and erect a perpendicular. Extend the drawn graph carefully in continuation with its trend beyond 1931, and let it cut the perpendicular at a certain point. The length of this ordinate after consulting the 'log-table will give the estimate of the population of 1941.

Extrapolation or forecasting will depend upon the constant rate of increase of the graph and on economic and other conditions governing the data.

For interpolation, in general plot the observations along the x axis and y -axis. Join the points by a freehand curve. To find a value of y corresponding to any value of x , erect a perpendicular through that point on x axis cutting the curve at a certain point. Read the value of this ordinate. This will be an estimate of the interpolated value. In time series the missing values for any particular year can thus approximately be found.

(8) *Graphs of Frequency Distributions*—Frequency distributions are represented graphically by (i) Histograms or Column diagrams or Block diagrams, (ii) Frequency polygons and frequency curve, (iii) Cumulative frequency curve.

(i) *Histogram*—Plot the class intervals along the axis of x , side by side. Take the first class interval and draw on it a rectangle with the corresponding frequency as height. Take the second class interval and draw a rectangle with its corresponding frequency as height along with the first rectangle. In this way draw all the rectangles along with each other for the whole frequency distribution. The set of rectangles so drawn will form a Histogram. This is in general use for a frequency distribution.

(ii) *Frequency polygon and curve*—Mark the central values of the class intervals along x axis, and plot the frequencies corresponding to the central values. Join the plotted points by means of straight lines, the figure so formed will be a frequency polygon. In a histogram if the middle points of the top horizontal sides of the rectangles are joined by straight lines the figure formed is a frequency polygon and if these middle points are joined by means of a smooth freehand curve, the curve formed is a frequency curve or smoothed histogram. This curve in most of the cases is bell shaped in form and is such that its area is approximately the same as that of the polygon or the rectangles. The diagram drawn on the annexed page is that of a Histogram and frequency curve. The middle points a, b, c, d & f when joined by lines will give a frequency polygon.

(iii) *Cumulative frequency curve or ogive*—Form the cumulative frequencies and plot these along the vertical line

Histogram and Frequency Curve

at the upper limits of the class intervals, marked along the horizontal axis. Join the plotted points by means of a freehand curve. The curve drawn will be a cumulative frequency curve or ogive.

For joining the points lines can also be drawn if the series is discrete but for continuous series where class intervals are small and number of observations great, freehand curve should be drawn.

The ogive is useful for locating graphically the Median, and Quartiles as follows. Along the vertical axis mark the total number of frequencies and also its middle point for median. From this middle point draw a line parallel to the x axis, cutting the ogive at certain point. The distance of this point from the vertical will give the value of the Median according to the scale used. In the same way, to obtain first and third Quartiles mark $\frac{1}{4}$ th and $\frac{3}{4}$ th distances instead of the middle point and proceed as for the median.

Interpolation may also be carried along the ogive. Deciles and Percentiles can also be located.

Example—To draw the cumulative frequency curve for the following frequency distribution and locate the Median.

Class intervals	Frequencies	Cumulative Frequencies
1-5	4	4
6-10	10	14
11-15	28	42
16-20	49	91
21-25	58	149
26-30	82	231
31-35	87	318
36-40	79	397
41-45	50	447
46-50	37	484
51-55	22	506

The adjoining diagram gives the cumulative frequency curve. The cumulatives are plotted against the upper limits of the class intervals 5 10 15 55. The points are joined by means of a freehand curve.

To locate the median mark the total frequencies 506 along the vertical OY and then its middle point. From this middle point draw a line parallel to the horizontal OX cutting the curve at the point. The distance of this point from the vertical will give the median value.

Percentage cumulative frequency curve—To draw this curve first express each frequency as a percentage of the total number then form the cumulatives and plot them as in the case of the ogive. The curve drawn will be a cumulative percentage frequency curve and the table formed will be a percentage frequency table.

The curve is useful for comparing and adjusting the distribution.

Histogram for unequal interval—If a frequency distribution consists of some equal class intervals and a few unequal class intervals the histogram can be drawn as follows.

Mark the class intervals along the x axis and erect rectangles on the class intervals of equal magnitude with their corresponding frequencies as ordinates. For unequal class intervals notice the relation of their magnitudes to the equal class intervals. If the unequal magnitudes are m times (or say) the equal magnitude then divide the frequencies corresponding to the unequal class intervals by m and taking these as Ordinates draw rectangles on the unequal class intervals. The set of rectangles so formed will be a Histogram (e.g. Exercise III 15).

Lorenz Curve and Pareto Curve

Lorenz curve is employed in order to measure the concentration of wealth or income. This curve takes the form of a cumulative percentage frequency curve combining the percentage of items under review with the percentage of wealth or other factor distributed among such items.

सूचक प्रमाण सूचक
Cumulative Frequency Curve

कोटि 6

It is useful for comparing the distribution of property over different groups of business and showing the effect of a group. The following example illustrates the method of the construction of the Lorenz Curve. Consider the following data relating to the distribution of estates exceeding £10,000 in net capital value.

Number and Capital Values of Estates in Great Britain liable to Estate Duty 1929-30

1 Capital value exceeding (1) (£000)	Cumulative Number of Estates (2)	Cumulative Percentage (3)	Cumulative Net Capital Values (4) (£000,000)	Column (5) as Percentages (5)
3,000	2	0.02	12.4	3.39
2,000	6	0.07	16.2	4.42
1,500	10	0.11	24.7	6.74
1,000	15	0.17	32.1	8.93
800	20	0.23	36	9.83
600	35	0.40	47.1	12.86
500	45	0.55	52.6	14.36
400	68	0.78	60.1	16.41
300	119	1.37	77.5	21.16
250	158	1.81	86.4	23.59
200	214	2.46	100	27.31
150	317	3.64	118.4	32.33
100	581	6.67	149.5	40.82
80	817	9.38	169.7	46.34
60	1,172	13.46	195.2	53.3
50	1,467	16.84	211.7	57.81
40	1,971	22.63	233.8	63.84

203 4

e Procedure —(a) Convert the cumulatives in column (2)
in percentages, total being 8710 if in column (2) cumu-
lative are not given then first take cumulative and then
percentages or first form the percentages and then take the
o cumulatives These are given in column (3)

1 (b) Convert column (4) into percentages, total being
3 366 2 If cumulatives are not given in any distribution take
) the cumulatives and then percentages.

15 Draw the graph of the cumulative percentages in
3 columns (3) and (5) The curve traced will be the Lorenz
1 Curve, as shown in the diagram

1 The straight line joining the extremities denotes the
2 line of equal or even distribution. The concavity of the
v curve away from the straight line is a measure of con-
centration of wealth

2 By drawing two or more Lorenz curves, we may
compare income distributions at different times or places

1 Pareto's Law —If a cumulative frequency distribution
of incomes be plotted upon a double logarithmic scale, the
points will lie approximately upon a straight line

1 This is Pareto's law after Pareto (Italian) This
statement is true of Great Britain, United States, Germany,
British India and other countries where it has been tested

1 The following table and graph illustrates the Pareto
1 Law, with reference to Great Britain and Northern Ireland.

Cumulative distribution of Incomes 1928 29.

Lorenz Curve

Pareto Curve
Year 1928-29

Income (x) (1)	Number of Incomes of £x, or over (y) (2)	Log (x) (3)	Log (y) (4)

1,00,000	130	5 0000	2 1139

1 Connor, page 200—203

Column (1) shows the income (x) and column (2) the number of incomes of £ x or over. Columns (3, and (4, show the logarithms of the figures in columns (1) and (2).

Plotting the logarithms we get Pareto's curve, which is approximately a straight line. The steeper the slope of the curve, the more equally is income distributed and vice versa.

Pareto's law is not recognised as a general law of income distribution. Pareto's curve can be used for interpolation¹⁰ and not for extrapolation. Mathematically the law is $y = ax^{-b}$, where y is the number of persons whose income¹¹ is at least x units (Rupees pound £s etc) a and b are con-

starts which depend on the country or the class of the community that is being considered. In logarithms, the equation can be written as

$\log y = \log a + b \log x$ b is the slope of the curve, its usual value being 1.5 nearly

Curves of the type $y = ax^b$ and $y = ab^x$

On a graph paper, any point may be taken as origin where the value of the variables x and y will be zero. The positive values of x and y are measured along the lines OX and OY respectively. The negative values of x and y are measured along OX' and OY' respectively. XOY is the first Quadrant having x and y positive.

A point is represented by the values of x and y and is written as (x, y)

In the first Quadrant XOY x and y are positives

In the second Quadrant YOX' , x is negative ($-ve$) but y positive ($+ve$)

In the third Quadrant $X'OY'$, x is -ve and y is - the point (pt) will be $(-x, -y)$

In the fourth Quadrant XOY' , x is +ve and y is - the pt. being $(x, -y)$ The value of x and y , $x = -3$ & $y = -4$ are called the co-ordinates of a point say P plotted in the fourth quadrant Such a graphical system known as Cartesian system.

In the curve $y = ax^b$, a and b are constants, but x & y are variable and can have any values In the equation $y = ax^b$, y depends upon x , so x is called the independent variable and y the dependant variable Let us consider a few well known cases of this general equation when b is positive, say $y = x$, $y = x^2$, $y = x^3$

Allot values to x , as shown,

To trace $y = x^2$, the values can be allotted as

x 0, 1, 2, 3, 4, 5, -1, -2, -3, -4, -5.

y 0, 1, 4, 9, 16, 25, 1, 4, 9, 16, 25

Plotting these points with co ordinate (0, 0) (1, 1), (2, 4) - we get the required graph, both the branches going at an indefinite distance or infinity, such a curve called the Parabola and the equation represents a Parabolic curve lying in the first and second quadrants. If the equation had been $y^2 = x$ the parabola will lie in the first and fourth Quadrants.

The graphs of curves $y = x^4$, $y = x^6$, $y = x^8$ i.e., of even powers of x , will all lie in the first and second Quadrants. The graphs of odd powers of x , i.e., of $y = x^3$, $y = x^5$ - will lie in the first and third Quadrants, and $y = x$ will represent a straight line

The above method of plotting curves is general and is applied for all curves in Cartesian system.

Exponential Curves—The curves given by, $y=ab^x$ are called Exponential curves. The curve is drawn by plotting the points, as shown in $y=4^x$

Points are x 0, $\frac{1}{2}$, 1, 2, 3,
 y 1, 2, 4, 16, 64,
 $-\frac{1}{2}$, -1,
 $\frac{1}{4}=5, \frac{1}{4}=25$.

Plotting out these values, the curve is found to lie in the first and second Quadrant. In this way exponential curves of the form, $y=ab^x$ can be drawn.

Exercise III

1. Draw a bar Diagram to represent the turnover of a company for 12 years

Rs. 35,000, 42,000, 43,500, 48,000, 48,500, 52,000,
 36,500, 54,500, 100,000, 54,000, 112,500, 194 000

2. The following table gives the Birth Rates and Death Rates per thousand of a few countries. Represent them by a Diagram (Sub divided)

Country	Birth Rate	Death Rate
India	33	24
Japan	32	19
Germany	16	10
Egypt	44	24
Australia	20	9
New Zealand	18	8
France	21	16
Russia	38	16

3, Draw a percentage bar diagram for Birth Rates Death Rates in Q. 2.

4 Represent the following figures about infant mortality in different cities by a suitable diagram,

London	Calcutta	Bombay	Naghpur	Madras	Par
66	244	274	323	251	93

5 Draw the graph of the following time series —

Years	Gross Profit Rs.	Expenses Rs.	Net π , Rs.
1	7,900	2,700	5,200
2	5,500	1,700	3,800
3	4,800	1,500	3,300
4	4,100	1,000	3,100
5	6,500	4,000	2,500
6	9,000	5,000	4,000
7	8,100	3,500	5,000
8	7,000	3,000	4,000
9	6,500	1,600	4,900
10	6,200	2,500	3,700

6 The following table gives details of the month expenditure of three families Represent them by a suitable diagram

Items of Expenditure	Family A		Family B		Family C	
	Rs.	a.	Rs.		Rs.	
Food	12	0	25		30	
Clothing	2	8	8		10	
House rent	2	0	4		8	
Education	1	0	5		7	
Miscellaneous	2	8	8		15	
Total	20	0	50		70	

This is an example of Rectangular Diagram.

7. Draw squares for the following table which give

the production of wheat of the following countries in a certain year.

Countries	Quintals (000,000)	
United Kingdom	12	
India	105	
Egypt	11	
U.S.A.	230	
Africa	3	
Canada	108	
U.S.S.R.	289	

U S S R U S A

8 Draw the following diagrams on a logarithmic scale for Q 8 and 9.

United Kingdom Receipts for Super Tax

Year.	1911,	1912,	1913	1914,	1915,	1916,

Acreage of crops

	(A) (000) acres	(B) acres
1920	1949	13050
1921	2040	8335
1922	2034	8415
1923	1799	16923
1924	1594	32637
1925	1550	56243

10 The following figures gives the quantity of sugar production in the following countries. Represent them (1) by circles (2) by sectors (3) by cubes

*Production of Sugar
in Quintals
(000,000)*

India		20
Egypt		1
Cuba	--	32
Java	.	30
Australia	..	5
Japan	--	1

11. Represent the data in Q. 15 (Ex. 1) by a suitable diagram

12. Draw Histogram, frequency polygon and curve for the data in Q. 16, 11 and 12 (Ex. 1).

13. Draw the frequency graph for Q. 23 (Ex. 1)

14. Draw the cumulative frequency curve for Q. 26, 27 and 24 (Ex. I) and locate the median and Quartiles. Compare the values obtained by actual calculation.

15. Data showing the Intelligence Ratios of 1000 children. Draw a Histogram.

125—139	23	85—89	139
115—124	40	80—84	133
110—119	37	75—79	89
105—109	71	65—74	83
100—104	90	45—64	29
95—99	134		
90—94	132		<hr/> 1000

Hint.—This is an example in which class intervals are written from the highest to the lowest. It is to be noticed that the last two class intervals are of unequal magnitude. Therefore the frequencies, for the purpose of drawing will be ; for 45—64, which will have a base four times, than the

equal interval (5) the frequency $\frac{1}{5} \times 29$, in order that its area may represent a frequency of 29. Similarly the height of the Bar angle representing the frequency of 65-74 will be $\frac{1}{5} \times 83$. Rectangles are to be drawn side by side.

16 Represent the following graphically

	(A)	(B)	Total
1935	130	370	500
1936	110	260	370
1937	134	256	390
1938	146	244	390
1939	159	285	445

Hint — This is a subdivided Bar diagram for each year with the given totals.

17 Draw a Histogram and frequency polygon for the following distribution

Degrees of cloudiness (x)	Frequency	Degrees of cloudiness (x)	Frequency
10	580	4	45
9	150	3	68
8	196	2	75
7	75	1	130
6	55	0	220
5	40		

Hint — Take x as the central values and then plot.

18 Draw a cumulative percentage frequency curve for Q 15

19 Draw the graphs of the following curves $y=x$,

$$y=x^3, y=x^4, y=\frac{1}{x}, x^2=y, y=2^x, y=\frac{1}{x^2}$$

✓ 20 Draw Lorenz curves for the comparison of profit of two groups A and B in business

<i>Total amount of profits earned by Companies in each Division</i>	<i>No of Companies in each Division</i>	
<i>Rs</i>	<i>Group A</i>	<i>Group B</i>
600	6	1
2500	11	19
6000	13	26
8400	14	14
10 500	15	14
15 000	17	13
17 000	10	6
40 000	14	

21 Construct an ogive curve for the following frequency distribution of Cotton Mills in Bombay according to the quantity of Cotton consumed and estimate the value of the median from the curve

<i>Cotton Consumed in thousand candies</i>	<i>No of Mills</i>	<i>Cotton Consumed in thousand candies</i>	<i>No of Mills</i>
0—2	5	10—12	4
2—4	13	12—14	1
4—6	12	14—16	3
6—8	11	16—18	1
8—10	8	18—20	1
		over 20	2
		(B A Hons 1941)	

22 Represent diagrammatically the following data regarding the operation of irrigation works in India

Province		Area irrigated in Acres
		Rabi (1926-27)
Madras	—	1,003,065
Bombay		1,128,594
Bengal		447
J P		1,778,645
Punjab		6,084,838
Bihar & Orissa		97,858
C P & Berar		9,165
N W F Province	—	182,574
Baluchistan	—	11,470
Jaipur Mewar	—	22,550

(B A Hon: 1941)

23 The following table gives the population of the United Kingdom and India at the time of the last seven censuses —

Years	Population in lacs	
	United Kingdom	India
1871	315	2062
1881	349	2539
1891	377	2873
1901	415	2944
1911	452	3152
1921	471	3189
1931	490	3515

Represent the above figures by curves in a logarithmic scale. Estimate the population for 1941

(M A 1939)

24 From the data given in Q 17 Exercise 1, draw the graph of the accumulated frequencies and hence obtain the value of the median

(*Indian Audit and Accounts Service Exam 1941.*)

25 Draw a cumulative frequency graph of the distribution given in Q 18, Exercise I, and calculate the values of the median and Quartiles (M A 1943)

26 Draw a Bar or Pie Diagram to represent the following data —

Output and cost of Production of Coal

<i>Cost per ton disposable commercially</i>	1924	1928
Wages —	12 74	7 95
Other costs	5 46	4 51
Royalties —	0 54	0 50
	<hr/>	<hr/>
Total	18 76	12 96
	<hr/>	<hr/>
Proceeds of Sale per ton	19 91	12 16
Profit (+) or loss (—) per ton	1 15	—0 80

(B A Hons 1943)

27 The following frequency distributions shows the number of live stock held by 100 farmers in a tahsil of Bombay Province Draw a graph showing the cumulative frequency curve for this distribution and find the two Quartiles and the median (M. A 1942)

Live stock units 1, 2, 3, 4, 5, 6, 7

Number of farmers 1, 13, 30, 25, 16, 9, 6 = 100

(M A 1942)

28 Represent graphically the following data for Capital outlay and Gross earnings of class I railways in India —

Years	(In Millions of pounds)	
	Capital outlay	Gross earnings
1923-24	464	70
1924-25	473	74
1925-26	487	73
1926-27	505	72
1927-28	594	86
1928-29	599	86
1929-30	617	84
1930-31	627	77
1931-32	631	71
1932-33	638	70
1933-34	635	72

(B.A. Honrs 1942)

29 The following 44 figures give in arbitrary units the measurements of hardness on different specimens of a certain aluminium die casting —

<i>Specimen</i>	<i>Hardness</i>	<i>Specimen</i>	<i>Hardness</i>
1	53.0	23	64.3
2	70.2	24	82.7
3	84.3	25	55.7
4	55.3	26	70.5
5	78.5	27	87.5
6	63.5	28	50.7
7	71.4	29	72.3
8	53.4	30	49.5
9	82.5	31	71.2
10	67.3	32	52.7
11	69.5	33	75.6
12	73	34	63.7
13	55.7	35	69.2
14	85.8	36	61.4
15	95.4	37	83.7
16	51.1	38	94.7
17	74.4	39	70.2
18	54.1	40	80.4
19	77.8	41	76.7
20	52.4	42	82.9
21	69.1	43	55.0
22	53.5	44	84.8

Group the data into a frequency distribution and draw the corresponding histogram and frequency polygon

(B.A. Hons 1942)

30 The following table gives the number of motor cars produced in three countries during the years 1929—1937 —

(Figures are given in thousands)

<i>Year</i>	<i>Germany</i>	<i>France,</i>	<i>United Kingdom</i>
1929	96	254	241
1930	74	231	241
1931	68	201	226
1932	50	172	246
1933	99	189	296
1934	172	187	355
1935	245	166	417
1936	302	203	481
1937	332	200	493

Represent the above figures by curves on the same graph paper and give necessary comments.

(M A 1941)

31 The following table gives the birth rate and death rate of a few countries of the world during the year 1937, —

<i>Name of country</i>	<i>Birth Rate</i>	<i>Death Rate</i>
Egypt —	43.5	27.2
Canada	19.8	10.2
United States	17.0	11.2
Mexico	40.0	23.9
Argentina	24.0	11.9
India	34.5	22.4
Japan	30.6	17.0
Germany	18.8	11.7
Austria	12.8	13.4
France —	14.7	15.0
Norway	15.3	10.4
England and Wales	14.9	12.4
Switzerland	15.0	11.3
Australia —	17.4	9.4

Represent the above figures by a suitable diagram

(M A 1941)

CHAPTER V

DISPERSION OR VARIABILITY AND SKEWNESS

The Average or the typical value is not of much use unless the degree of Variation which occurs about it is known in other words, it should be known as to what extent the average is typical, or how the items vary in size

✓ { Dispersion or Scatter or Variation or Variability is a Measure of the extent to which the individual items vary the scatter about the measure of central tendency is large, it is of little use as a typical value

Measures of Dispersion are also called Averages of the second order

Measures of Dispersion are

(1) The Range, (2) Quartile Deviation or Semi inter quartile Range, (3) Mean Deviation or Average Deviation, (4) Standard Deviation,

The Range, the simplest of the Measures, is the difference between the minimum and maximum (smallest and the largest) items in a series. As the range depends upon size of extreme items, it is not a satisfactory measure of Dispersion

In the series 60, 61, 63, 65, 67, 68, 90

Range is $90 - 60 = 30$

(2) Quartile Deviation or Semi interquartile range is given by $\frac{Q_3 - Q_1}{2}$, where Q_1 and Q_3 are the lower and upper quartiles

(3) Mean Deviation is generally calculated from the median. It can also be calculated from the Arithmetic Mean. It is the average of the deviations of the items from the Median or Mean deviations being taken positively or Mean

Deviation = $\frac{\sum |d|}{n}$ where d stands for deviation from Median or (Mean) *taken positively*, neglecting negative signs, n being the number of items in the series. For grouped data, Mean Deviation = $\frac{\sum f |d|}{n}$ where d stands for deviation of the central values from the Median or Mean n being the sum of frequencies

$|d|$ indicates deviations taken positively

Example 7. *Example 7*

Class intervals	Central values	d	frequencies	$f d$
2-4	3	-2	3	6
4-6	5	0	4	0
6-8	7	2	2	4
8-10	9	4	1	4
			10	14

Median = $4 + \frac{1}{2}(5 - 3) = 5$ and

$$M.D. = \frac{\sum f |d|}{n} = \frac{14}{10} = 1.4$$

In a frequency distribution with unequal class intervals the Arith. Mean instead of the Median should be used

Standard Deviation and Variance — Standard Deviation is calculated from the Arith. Mean. It is given by the formula (1) for ungrouped data

$$s.d. \text{ or } \sigma \text{ or } S = \sqrt{\frac{\sum d^2}{n}}, \text{ where } d \text{ stands for deviations}$$

of the items from the Arithmetic Mean is being the sum of items (2) for grouped data

$$\sigma \text{ or } S = \sqrt{\frac{\sum f(d)^2}{n}} \text{ where } d \text{ stands for the deviation}$$

of the central values from the Arithmetic Mean n being the sum of all the frequencies $= \sum f$ The square of the standard deviation is called Variance *Now*

Ex 2 — To find σ for 1 2 3, 4 and 5 Arithmetic Mean $= \frac{1+2+3+4+5}{5} = 3$ Squares of the deviations of these items from 3
 $+1 \ 0, \ 1 \ 4$

$$\sigma^2 = \frac{4+1+0+1+4}{5} = 2 \quad S.d \text{ or } \sigma = \sqrt{2} = 1.414$$

Ex 3 — To find the Variance and standard deviation the following frequency distribution —

	<i>mean</i> x	f		d	d^2	fd^2
1—3	2	40	40	-2	4	160
3—5	4	30	120	0	0	0
5—7	6	20	120	2	4	80
7—9	8	10	80	4	16	160
		<u>100</u>				<u>400</u>

$$\text{Here Arithmetic Mean} = \frac{\sum fx}{\sum f} = \frac{400}{100} = 4$$

$$\sum fd = 400^0 \text{ and } n = \sum f = 100$$

$$\text{Variance } \sigma^2 = \frac{400}{100} = 4 \text{ and } \checkmark$$

$$\text{Standard deviation } \sigma = 2$$

Short cut method for finding the Standard Deviation

The short cut method avoids the labour of finding the Arithmetic Mean. Any convenient Provisional Mean can be taken and the following formula is then used

$$\sigma = \sqrt{\frac{\sum f(D^2)}{n} - \left(\frac{\sum fD}{n}\right)^2} \text{ where } D \text{ stands for deviations}$$

of the central values from the Provisional Mean

In the case of the ungrouped data, the above formula is used without f D being the deviations of the items, from Provisional Mean n being the total number of items i.e.

$$\sigma^2 = \frac{\sum D^2}{n} - \left(\frac{\sum D}{n}\right)^2$$

Example 3 can be solved by taking a Provisional Mean say 6 thus

	f	D	fD	D^2	$f(D)^2$
x					
2	40	-4	-160	16	640
4	30	-2	-60	4	120
6	20	0	0	0	0
8	10	2	20	4	40
	<u>100</u>		<u>-200</u>		<u>800</u>

$$\text{Now } \sigma^2 = \frac{800}{100} - \left(-\frac{200}{100}\right)^2 = 8 - 4 = 4$$

therefore () $\sigma = 2$ as before

Characteristics of standard deviation

The σ is affected by the value of each item. It is the best measure of dispersion. It is the least erratic, is suitable for arithmetic and algebraic manipulation and is used for higher statistical operations while the Mean Deviation is not further used.

Quartile Deviation is easier to calculate than standard deviation, but it is liable to be erratic.

Relative Measures of Dispersion

The measures given above are absolute measures of dispersion and the resulting values cannot always be compared with significance

To relate the measure of dispersion to its average to convert it to percentage form the standard deviation divided by Arithmetic Mean. This measure is known as **Coefficient of Variation** given by $CV = \frac{100\sigma}{\text{Mean}}$ and is generally used for comparison of Variations or Variability of two or more quantities. $\frac{\sigma}{\text{Mean}}$ is called the coefficient

Standard Deviation. In Example 3 $CV = \frac{100 \times 2}{4} = 50$

Other comparative coefficients of dispersion are

$$\text{Quartile coefficient of Dispersion} = \frac{Q_3 - Q_1}{Q_3 + Q_1} \times 100 \quad \checkmark$$

Mean coefficient of Dispersion

$$= \frac{\text{Mean Deviation} \times 100}{\text{Median or Arithmetic Mean if used}}$$

Skewness — Besides Average and Dispersion skewness is also a measure to study the distributions. Skewness is a term for the degree of distortion from symmetry. When a distribution is symmetrical the values of the Mean, Median and Mode coincide. Skewness has the effect of pulling the median and Mean away from the Mode sometimes to the right and sometimes to the left. When the Mean is greater than the Mode Skewness is said to be positive. It is negative when Mean is less than the mode.

A large number of frequency distributions occurring in

practice, fall into four types —the symmetrical, the moderately skewed or asymmetrical, the extremely skewed or J-shaped, (in the form of alphabet J), and the U-shaped type (in the form of the alphabet U).

The figure for symmetrical curve will be found in Normal Curve. (See Chap. XI) The somewhat departure for this shape will give a moderately skewed curve

The co-efficient of skewness that is the measure of skewness commonly used is given by the formula

$$(1) S_k = \frac{\text{Mean} - \text{Mode}}{\sigma} \text{ or } \frac{3(\text{Mean} - \text{Median})}{\sigma}$$

For a symmetrical distribution, the co efficient of skewness will be zero.

The second formula is based upon the fact that in a skewed distribution the median does not lie exactly half way between the Quartiles

The co-efficient is also given by

$$\frac{Q_3 + Q_1 - 2 \text{ Median}}{Q_3 - Q_1}$$

The two methods are based on entirely different principles and the results obtained will be different

For a symmetrical and moderately skewed distributions, mean deviation is about $\frac{1}{2}$ standard deviation and the Quartile Deviation is $\frac{2}{3} \sigma$ (approximately).

Exercise IV

	Weekly Wages	Workers
1 — Find the mean deviation and mean co efficient of Dispersion for	Rs 2 4	20
	.. 4 6	40
	.. 6-8	30
	.. 8-10	10
		Ans $\frac{3}{2}$; 27

II.—Find the average deviation and the standard deviation of the following —

$$\underline{n=8}$$

(a) Rs 300, 400, 700, 200, 600, 500, 100.

(b) Rs 120, 60, 80, 20, 100, 40, 140.

Ans (a) Rs 171.4, $\sigma = ?$

(b) 34.28, $\sigma =$

III.—Find the standard deviation of the height of 10 men in inches 64, 65, 73, 70, 70, 70, 69, 68, 66, 75

Ans 3.15 in

IV.—Calculate the Mean deviation (M.D.) from the Median and the Mean, and compare with the standard deviation.

Rs 20, 18, 16, 14, 12, 10, 8, 6.

Frequencies 2, 4, 9, 18, 27, 25, 14, 1.

Ans Median, $\overset{\text{A Mean}}{M.D.}$, $\overset{\text{M.D.}}{A \text{ Mean}}$, $\overset{\text{M.D.}}{M.D.}$, $\overset{\text{M.D.}}{\sigma}$
 $\times 11.74$, $\times 12$, 2.24 , 2.11

V.—Compute the S.D. and Q.D. coefficient of variation and of skewness for the frequency distribution of wages

Monthly Wages	No of Wage earners
Rs. 12.5—17.5	2
" 17.5—22.5	22
" 22.5—27.5	19
" 27.5—32.5	14
" 32.5—37.5	3
" 37.5—42.5	4
" 42.5—47.5	6
" 47.5—52.5	1
" 52.5—57.5	1

(H Sc., Agr. 11.
1943)

Punjab University:

$\sigma = 8.85$

CV = 31.8, ✓

QD = 5.145, ✓

SK = .7 nearly

VI — Calculate the mean and standard deviation of the following values of the World's annual gold output (in millions of pounds) for 20 different years —

94 95 96, 93, 87, 79 73 69, 68, 67, 78 82 83, 89, 95, 103, 108, 117, 130, 97.

Also calculate the percentage of cases lying outside the mean at distances $\pm S$, $\pm 2S$, $\pm 3S$, where S denotes standard deviation

(B A Hons 1942).

Ans Mean, 90.15 S = 10.59 35%, 5, and 0.

VII — From the following frequency table of Marks obtained in Practical Exam Calculate the co-efficient of skewness.

Marks	10	11	12	13	14	15	16	17	18
Candidates	26,	201,	673,	1001,	739,	310	80	13	1

(Aligarh M.A., 1938) *Ans 108*

VIII.—In Q. 18 Ex 1 find the standard deviation and the mean Deviation

(M A 1943) *Ans 543, '432*

IX — Calculate the standard deviation of the chest measurements in Q. 19, Ex 1

Ans. 2.05.

(Punjab M A. 1943. Aligarh M.A. 1941.)

X.—Obtain the standard deviation for the distribution given in Q. 17, Ex. I.

(Indian Audit and Accts Exam 1941) *Ans 5.52.*

XI.—Compute the standard deviation of the rainfall in — — districts of Rawal from the following

District
Rainfall in inches
(1939 July)

24-Parganas, Murshidabad,
17'36 19'17

Khul, Bardwan, Midnapur,
22'99, 17 14'19

Rajshai Dacca, Chittagong,
21'23 27'10 40'97

Cooch-Bihar, Hoogly
26'58 17'67

(B.A Hons. 1941) Ans 7 356

XII — Calculate the co-efficient of variation for the production of Motor-cars. Germany, France and United Kingdom, data given in Q 30 Exercise III

(M.A 1941.) Ans 63.59, 13.01, 30.35.

XIII — Data for Weekly Records of Temperature (Fahrenheit).

Temperature limits	25.5—29.5,	29.5—33.5	33.5—37.5,
Records	1	1	9
	37.5—41.5,	41.5—45.5	
	11.5	28	
	45.5—49.5, . . .		
	31.5,	36.5,	30.5, 31.5, 30, 26,
	77.5—81.5		
	13.5, 4,	3	

Compute the mean, median, standard deviation, quartile deviation.

Ans 55.1, 54.9, 10.33, 7.9

XIV.— x	f	x	f
3	5	38	79
8	9	43	50
13	28	48	37
18	49	53	21
23	58	58	6
28	82	63	3

XV — Calculate the standard deviation and coefficient of variation for

Marks	10-20,	20-30,	30-40,	40-50,	50-60,	60-70,	70-80
No of students	5	12	15	20	10	4	2

Represent the data graphically.

(Hyderabad University B A 1946)

Ans. $\sigma = 14.3$

$cv = 85.2\%$

XVI — Compute the Quartile Deviation and coefficient of variation for the data in Q 29 Ex I Also determine the value of quartile deviation graphically

(Indian Audit and Accnts. Exam. 1945).

Ans. 13.54, 12.24

XVII.—The following is the frequency distribution of percentage butter fat, in samples of milk of individual cows in a herd Calculate any one of the three measures of dispersion state the relative merits of the three as measures of a distribution Percentage butter fat, 2—2.4, 2.4—2.8, 2.8—3.2

3.2—3.6

Frequency 1, 4, 6, 19, 63, 85, 111, 95, 79, 53, 28, 16, 12, 9, 1, 2, 0, 2

(Indian Audit and Accnts 1943) Ans $\sigma = 9.5$ nearly

XVIII.—Calculate the standard deviation for the following data of 'Difference in age between husband and wife in a particular community.

Difference in years	0—10,	10—15,	15—20	20—25,	25—30,
Frequency	700	507	281	109	52
	30—35,	35—40			
	16	4			

(B Com 1945) Ans. 6.77.

XIX — Compute the standard deviation for Q 27 (Ex 1)
(H₃derabad 1945)

Ans 100

XX — Given sales as Rs 230 397 582 799 1035 for
5 years in 1927—35

Find the coefficient of variation

(B Com Supp. 1945) Ans 46

XXI — The following table gives the index numbers
wholesale prices of cotton manufactures and wheat in India
for ten months, from January 1943 to October 1943. Indicate
which of the two goods had more variable price

Prices for week ending 19th August 1939 = 100

[Capital June 29, 1944]

Index of Cotton	415, 427, 437, 469, 505, 513, 493, 426, 417
Index of Wheat	252, 332, 312, 308, 323, 330, 316, 371, 380

(B A Hons 1945) Ans Wheat

CHAPTER VI

INDEX NUMBERS

An index number is a statistical device for estimating the relative movements of a variate, in cases where measurements of its actual movements are inconvenient or not possible. Index Numbers have gained great importance in almost all branches of scientific inquiry. We may have index number for prices, cost of living, index numbers showing changes in employment, production, investment, industrial activity, business conditions, health and academic grades etc.

The index number will measure fluctuations during intervals of time, group differences of geographical position and degree, and it cannot do more than show a general tendency.

Construction of Index Numbers—The technique of index number construction involves the following processes

(a) Choice of items to be included. The items selected should be representative of the tastes, habits, or requirements of the class of the purchaser concerned. The number of items should be fairly large. To compare changes in the general level of prices in a given period of time, we should have

(1) Selection of representative Commodities

(2) Selection of representative places for each Commodity

(3) Regular and reliable quotation of prices from the representative places of commodities. Wholesale

(b) The form of Average to be used

(c) The selection of the Base

(d) The weighting system. The designation of the degree of relative importance of each constituent item is known as weighting

For simple Index Numbers, the first three methods are sufficient

Choice of Base—With the Fixed Base method, a definite year or average of a period of years is chosen and adhered to for a long time. The period selected should be a period of normal conditions and free from fluctuations and disturbances likely to affect the index. This Base is taken as 100, the price for this is taken as basic for the purpose of calculating Index Number

Index Number for a particular year

$$= \frac{\text{Price of the particular year}}{\text{Basic price}} \times 100$$

If the base price is Rs 5, then Index of a particular year when price is Rs 8 is $\frac{8}{5} \times 100 = 160$. This is also called a 'Relative' or the Percentage price and combination of such relatives is called the 'Index Number' in the general term. Add all the relatives and divide by the number of items to get the general Index or Index Number of Prices for the commodities

Example — Given

Commodity	Relatives during the years		
	1914 (Base = 100)	1923	1931
Wheat	100	170	72
Rice	100	192	70
Sugar	100	195	95
Ghee	100	187	92
Wood (Fuel)	100	185	92
Gold	100	150	180
Index Number of Prices	$\frac{600}{6}$ = 100	$\frac{1079}{6}$ = 179.8	$\frac{601}{6}$ = 100.1

Here we have used arithmetic mean as the average, if the geometric mean is to be applied, then the Index number will be obtained by multiplying the relatives and then taking the 6th root as the number of commodities in our example is 6 (in general n th root, where n is the number of commodities). Logarithms should be used for large numbers. Harmonic Mean and Median can also be used as an Average but in practice, Arithmetic Mean and Geometric Mean are frequently used, Geometric, being preferred for giving better results.

Chain Base Method.—With the chain base method, each year is calculated upon the preceding year as the base and the results are linked together afterwards as shown in the example.

'Statist' Index of Sugar, Tea and Coffee using Chain Base system, Relatives given,

Year	Sugar I	Sugar II	Coffee	Tea	Total	Average	Chain Index
1921	815	775	119	55	332	$\frac{332}{4} = 83$	83
1922	62	54	128	82	326	81.5	83×100
	76	70	108	149	403	100.8	100
1923	104	87	111	100	402	100.5	83.7×13
	168	161	87	122	538	134.5	100
							$= 111$

Explanation—Given the Relatives for 1921, 1922, 1923, for four commodities Find the Average for each year. Take the year 1921 and 1922. Taking 1921, as the base with chain index 83, construct relatives for 1922, so for Sugar I we shall have $\frac{62 \times 100}{81} = 76$ nearly. Similarly for other commodities we have 70, 108 and 149. Take the average of these which is 100.8. Multiply this average by the change index of 1921 and divide by 100 to get the chain index for 1922 which is $\frac{83 \times 100.8}{100} = 83.7$ ✓

Next, find the Relatives for 1923 taking 1922 as the base, we get for Sugar I $\frac{104 \times 100}{62} = 168$ ✓ and so on. Take the average of these and multiply it by the chain index of 1922, thus we get chain index for 1923,

$$= \frac{134.5 \times 83.7}{100} = 112.5$$

In this way we proceed further chaining each year with the preceding.

Chain base method provides a direct comparison of

ween each year and the next, which is more interesting to commercial people than indirect comparison through the medium of a possibly remote base

Weighted Index Numbers

There are two methods of weighting the indices of prices

(a) Weighted Aggregate of actual prices — When actual prices of the commodities or item are given and also the quantity of each item the quantities produced in some fixed period such as the base year may be used as weights

The index is obtained by comparing the weighted aggregate (total) for the given year to that of the base year. The formula for index number (Base year weighting) is

$$\frac{\sum p_1 q_0}{\sum p_0 q_0}$$
 where p_1 represents the prices for the current year for which the Index is required, thus for one particular year p_1 , for second p_2 ,

q_0 represents actual quantity of the base year for each item

p_0 represents the actual price of the base year for each item

To find the index for a particular year, multiply the price of that year with the corresponding quantity for the base year and add the products for all the items. Divide this sum by the sum of the products $p_0 \times q_0$. Multiply the result by 100 to get the Index Number

However, since conditions change, the quantity of the

commodities produced in any one fixed period will not
a good measure of their relative importance for all
periods. To meet this objection a set of weights which
 change every year may be used. Thus the quantity q
 in each given year may be used as weights when con-
 structing the index number for that particular period

The formula can then be written as (current
 weighting)

$$\frac{\sum(p_n q_n)}{\sum(p_0 q_n)}$$
 where q_n represents the quantity for
 particular year and p_n its price. So for first year we can have
 q_1 the quantity and p_1 the price, for second year p_2 and q_2 its
 quantity and price respectively

If fixed weights are used, the formula will be

$$\frac{\sum w p_n}{\sum w p_0}$$
 where w stands for the weights. If rela-
 tives and weights are given the weighted Index No. is obtained
 by multiplying the two and dividing the sum of products by
 sum of weights

The above formulæ are suitable for use with either the
 fixed or the chain base methods. They are to be multiplied by
 100 to get the Index Number

Fisher's Ideal Formula.—It is the geometric mean of
 the first two formulæ Index for a year

$$= \sqrt{\frac{\sum q_0 p_n}{\sum q_0 p_0} \times \frac{\sum q_n p_n}{\sum q_n p_0}}$$

This is also called a cross-weight formula.

There are over 150 formulæ for Index Numbers but here
 we have given the widely used ones, which may be used
 according to the nature of the data

(b) Weighted Average of Relatives or Ratios, Method

In this method the price relatives play the part and not the actual prices as in the former method. The formula with base year weights,

$$\frac{\sum \left[\frac{p}{p_0} \times (p_0 q_0) \right]}{\sum (p_0 q_0)}$$

Here the price relatives $\left(\frac{p}{p_0} \right)$ are weighted by total expenditure $(p_0 q_0)$

Through cancellation this formula reduces to

$$\frac{\sum (p_n q_0)}{\sum (p_0 q_0)}$$

If current year or given year weights are used the formula is

$$\frac{\sum \left[\frac{p_n}{p_0} \times (p_n q_n) \right]}{\sum (p_n q_n)}$$

For one year with p , price and q , the quantity

$$= \frac{\sum \left[\frac{p_1}{p_0} \times (p_1 q_1) \right]}{\sum (p_1 q_1)}$$

Index Number Tests—There are two fundamental methods for testing the consistency of the Index Number

(1) Time Reversal Test—Let the index of a year say 1930, computed with base (1928=100) be 200 reconstructing the Index Number for 1928 with base 1930, the index should be, by Time reversal equal to reciprocal of 200, i.e., $\frac{1}{2} = .5$

	1928	1930
Index	100	200
	.5	100

Cross-multiplying the index numbers should give a value of 1'00, since there are reciprocals. The test may be as; If the time subscripts of a price or (quantity) index number formula, be interchanged, the resulting price (quantity) formula should be reciprocal of the original formula

Take the formula $\frac{\sum p_n q_0}{\sum p_0 q_0}$ and change the time

scripts, it becomes $\frac{\sum p_0 q_n}{\sum p_0 q_0}$. Multiplying the two the result is not equal to unity (one). }

The Arithmetic Average of Relatives is not reversible. The result of calculating the current year upon the base year does not agree with the result of calculating the base year upon the current year. The product of the two is greater than 1 and not equal to 1 as it ought to be.

The simple geometric mean is reversible. With the geometric mean, the fixed base and chain base method agree, though it is rather troublesome to calculate the geometric mean.

Fisher's ideal Index Number meets the test.

Factor Reversal Test.—The index of prices can be obtained by any of the methods, for example, take a formula $\frac{\sum p_n q_0}{\sum (p_0 q_0)}$.

An index of the quantity of production can be obtained by reversing the position of the price figures (p) with the quantity figure (q) and so it is

$$\frac{\sum (q_n p_0)}{\sum (q_0 p_0)}$$

The factor reversal test says that

$$\frac{\sum p_n q_0}{\sum p_0 q_0} \times \frac{\sum(q_n p_0)}{\sum(q_0 p_0)} \text{ should be } = \frac{\sum p_n q_n}{\sum p_0 q_0},$$

i.e., if p and q factors be interchanged in a formula the product of the two should be equal to $\frac{\sum p_n q_n}{\sum p_0 q_0}$

Fisher's Ideal Index Number

$$\sqrt{\frac{\sum p_n q_0}{\sum p_0 q_0} \times \frac{\sum p_n q_n}{\sum p_0 q_n}} \text{ transforms itself into}$$

$$(\text{by interchanging } p \text{ and } q) \sqrt{\frac{\sum q_n p_0}{\sum q_0 p_0} \times \frac{\sum q_n p_n}{\sum q_0 p_n}}$$

Multiplying the two ideal indices, the result is

$$= \frac{\sum p_n q_n}{\sum p_0 q_0}.$$

Fisher's Ideal Index Number is called ideal, as it meets both the tests

Quantity Index Numbers — The Index Numbers can be used to measure changes in quantity groups as well as price changes. Index Numbers of this type are applicable to the measurement of changes in business activity, industrial production, etc. The method of construction is the same for Quantity Index Numbers as for Index Numbers of prices.

The simplest form is $\frac{\sum q_n}{\sum q_0} \times 100$

Where $\sum q_n$ denotes the sum of the quantities in any current or given year

$\sum q_0$ denotes the sum of the quantities in the base year

The weighted aggregate form for measurement of quantity changes is $\frac{\sum p_0 q_n}{\sum(p_0 p_0)}$ with base year weights (where p_0 may be the price or some weights),

and $\frac{\sum p_n q_n}{\sum p_n q_0}$ with current or given year weights.

Exercise V

I.—Years	1930,	1931,	1932,	1933,	1934,
Price of wheat per maund	Rs 4	5	6	7	7-8-0
	1940,	1941,	1942,	1943,	
	10	9	10	11	

Find the Index Number (1) by taking 1930 as the Base (2) the average of the first three years as base (3) 1940 as Base

Ans. (1) 100, 125, 150, 175, 187.5, 250, 225, 250, 275

(2) 80, 100, 120, 140, 150, 200, 180, 200, 220

(3) 40, 50, 60, 70, 75, 100, 90, 100, 110.

II.—Years	1921,	1922,	1923,
Bank Deposit Rs	0000, 34,845	37,194	40,034
	1924, 1925,	1926,	1927
	42,954 46,766	48,882	51,133

Calculate the Index Numbers for the Deposits for each year taking 1921 as base, in round figures.

Ans. 100, 107, 115, 123, 134, 140 and 147.

III.—Find the Index of Bank clearings and of Immigrants from the following data taking the average as the base, in round figures

Year.	Bank clearings in Million of Rs	Immigrants in tens of thousands
1	49	79
2	40	52
3	25	33
4	35	55
5	35	46
6	34	62
7	28	34
8	34	31

Ans 140, 114, 71, 100, 100, 97, 80, 97,
161, 106, 67, 112, 94, 126, 60, 67

IV.—Compare the following prices of Wheat and Coal as to their relative changes for the period 1913—20 Taking 1913 as base find the Index Number for each year for each commodity

		1913,	1914,	1915,	1916,
Price of wheat	Rs.	3 11 6	4-6 6	5-6-0	4-13-0
per maund	annas etc				
Coal p-r	ton	Rs	6-10 0	6-12 0	6 15 0
			7 0 0		
		1917,	1918,	1919,	1920
		4 12 6,	5 9 6,	8 3 6,	7 0 0
		7-1 0,	7-3 0,	7-10 0	7 8 0
Ans	Wheat	100, 119, 144,	130, 129,	151, 221,	188
	Coal	100, 102, 103,	106, 107, 109	115,	113

V.—Calculation of Statist Index of wholesale prices of Minerals

Year average.	Iron shillings and pence per ton		Bars Common £ per ton	Copper Standard £ per ton	Tin straits £ per ton	Lead £ per ton	Coal shillings per ton.	Coal average Export Price shillings per ton
	A	B						
1867—77	69.0	60.0	8½	75	105	20½	22	12.5
1913	65.6	58.3	7½	68	201	19½	21½	13.94
1921	168.6	137.4	19½	69½	171	24½	32½	34.83
1924	96.8	88.2	12½	63½	251	35½	27½	23.38
1930	76.0	67.0	9½	54½	144½	19½	24½	16.64

Taking 1867—77 as the base, calculate the Index Number of Minerals for each year, using arithmetic mean upto two places of decimals.

Ans. 110.65, 180.99, 157.87, 111.95

Hint—First find the relatives.

VI.—In Q V, calculate the Index Numbers (1) for 1921, taking 1913 as the base and (2) for 1913, with 1921 as the base

(1) 246.4, 246.77 101.95 85.08, 126.54 150 249.86

(2) 40.59, 40.52 98.08 117.54 79.07 66.67, 40.02

VII—In Q V, determine the Index Number for Minerals by taking the Geometric Mean of the Relatives

Ans 106.9, 169.2 151, 111.4.

VIII—In the solved example on chain base method, find the Chain Index for the years 1924—28 given

1924	93	75	154	96
1925	60	43	165	88
1926	60	44	159	89
1927	62	47	139	84
1928	51	40	146	77

Ans 115.3, 92.8 100, 90.8, 82.6

IX—In Q VI, find the Index Number of Minerals and test the Index Numbers by the Time Reversal Test

Ans (1, 172.37, (2) 68.92,

Product of Indices 118 *Not Consistent*

X—Find the Quantity Index Number for the following data with 1932 as the base

Year	Quantities	
	A	B
1932	9	7
1933	10.3	9
1934	11.0	6.7
1935	10.5	9.4
1936	12	4.5
1937	9.5	5.4
1938	8.9	9

Use the first formula given in Quantity Index Nos

*Ans (in round figures,
100 121, 111, 124, 103, 93 and 112).*

XI — Explain the methods used in constructing the Index Numbers of wholesale prices, or of the cost of living giving illustrations. Define an Index Number and explain the role of 'weights' in the construction of an index of the general price level

(B A Hons , M A 1942, 1943, 1945 , B. Com 1945)

XII — Explain with illustrations what is understood by an Index Number ?

Discuss the relative advantages of (1) Arithmetic Mean, (2) Geometric Mean, (3) Harmonic Mean, in the construction of an Index Number

(Indian Audit and Accounts, 1941)

XIII — Find the cost of living Index Number for the working classes from the data in Q XIII and Q XIV

Articles	Quantity Consumed in 1914 (Base) q_0 in Crores	$p_0 \times q_0$ for 1914, Rupees in Crores	$\frac{q_1 p_0}{p_1}$ is price for 1924
Pulses	13 mannds	60	70
Cereals	108 "	583	746
Food Articles	46 "	381	728
Firewood and Coal.	50 "	60	101

XVI — Use formulae (b) to find the Index for 1927 in
Q XV

Ans 110.5, 114.5

XVII — Apply Tests to XV

XVIII — It is desired to find the difference in the cost of living in the years 1939 and 1943 in the case of (i) Clerks (ii) industrial labourers in a big industrial town

Explain fully the necessary procedure to be adopted

(B Com 1945 Supp)

XIX — Distinguish between Fixed Base and Chain Base methods of constructing Index Numbers giving examples

Describe the various methods of weighting the index numbers of prices

How can the Index of Indian industrial activity be constructed?

(Indian Audit & Accounts Exam 1945)

XX — What is an index number? What are (1) time reversal test and factor reversal test? State their use

(C St & M A 1945.)

CHAPTER VII

ANALYSIS OF TIME SERIES

The analysis of Time Series involves the description and measurements of the various movements or changes as they come in the series during a period of time. The characteristics of a time series are to be found in its trends and fluctuations which are described here very briefly

1. **Secular Trend** or the long time growth or decline, existing within the data. It is a smooth, regular and long term movement of a statistical series. Most series of economic statistics exhibit definite trends. Such a trend may be constant in direction or may change direction at a constant rate. Thus the volume of production or sales of business house over a period of years shows a fairly regular growth. The same is the case with population of a country.

2. **Fluctuations in time series** may be regular or irregular. **Regular fluctuations** are (1) long term fluctuations (i.e. the Trend) (2) Periodic or moderately long period fluctuations, (3) Short term fluctuations or seasonal variations, which are more or less regular movements within the twelve month period and due to the changing seasons, consumption and production of commodities, interest rates, etc. are marked by seasonal swings repeated with minor variations year after year.

3. **Cyclical movements** or the swing from prosperity through recession, adversity, recovery and then on to prosperity again. One cycle is said to be completed when beginning with a peak, the falling curve reaches a minimum point and then rising again reaches the next peak. This is the case with price fluctuations.

4. **Residual, accidental or random Variations**, including unusual disturbances catastrophic or unexpected events such as wars, disasters, famines, strikes, floods.

Measurement of a Trend

The following methods are commonly used to measure trends.

(1) Freehand drawing (2) Semi average (3) average (4) Fitting a curve by least squares, which is explained in the next chapter on 'Curve Fitting (VIII)

1 *Freehand drawing*—First of all draw the graph of the given time series, with the time along the horizontal axis. Draw a smooth freehand line (or curve) approximately carefully in such a way as to describe what appears to be a long period movement.

2 *Semi average method*—In this method break the data into two equal parts and mark the middle years of each (if the number is odd, taken two parts approximately equal). Take the average of each part. Plot these averages at the mid-points of their respective periods. Join the two points drawn, this line will show the trend.

3 *Moving Average Method* is used for smoothing fluctuations in curves and to exhibit a trend with the help of averages in years. Smoothing brings out tendencies. The moving Average may be for three five six seven or more years and so on according to the size of the data. For three years moving average take the average of the first three years and place it against the middle year of the three. Leave the first year and then take the average of the next three years and place it against the middle of these three years. Proceed in this way taking the average after leaving one preceding year. Then plot these moving averages along with time series graph. This will be a moving Average graph showing the Trend. For a five year moving average take the average of the first five years and place it against the middle year of the five years, i.e., the third year. Then take the average of the next five years and place it against the middle year of the next five years, i.e., the eighth year. Proceed in this way.

middle year. Then take against the next five years leaving the first year and place it in the middle year of these. Proceed in this way and draw the curve. For a moving average of even years say four take the average of the first four years and place it against the middle $\frac{1}{2}$, between second and third year. Leaving the first year, take the average of the next four years and place in the middle of these. Proceed in this way and then draw the Trend Graph. A seven year cycle may be eliminated by means of a moving Average based upon a period of 7, 14 years the greater the number of years the smoother the curve.

Example 1—Years		Values	3 Year Moving Total	3 Year Moving Average
1921	8			
1922	6		21	7
1923	7		24	8
1924	11		30	10
1925	12		37	12.3
1926	14		41	13.66
1927	15		48	16
1928	19			

When an even number of items is included in the moving average, say six the centre point of the group lies between two years. It is necessary to adjust these x year moving averages so that they coincide with years. Take a two years moving average of the six years average. The resulting average is located between the two six year moving average values and, therefore, coincides with the years. The final result is said to be a six year moving average centred

<i>Example 2.—Year.</i>	<i>Values.</i>	<i>Six year Moving average.</i>	<i>Two year Moving Total of Col 3.</i>	<i>Six Mov Av. Ct</i>
(1)	(2)	(3)		
1924	16			
1925	17			
1926	25			
		32		
1927	35		68 66	34'33
		36'66		
1928	46		78 82	39'41
		42'16		
1929	53			
1930	44			
1931	50			

The Moving average is quite simple for calculation and especially useful in making approximations of general movements in a series particularly eliminating a large part of a cycle that is rather regular. A moving average cannot be brought up-to-date, as, depending upon the number of items included, the last point in trend occurs a few years before the end of the data.

Moving Average and seasonal variations—Moving Averages provide a useful method for isolating seasonal variations. First of all take the moving average for months, centred (adjusted by two month-moving average for all the years. Express the original data as percentages of the corresponding moving averages. Take the average (arithmetic or median) of the percentages for each month (dividing by the number of years for Mean).

These will be the Indices of seasonal Variation

each month. The average of the 12 Means for 12 months ought to be 100 otherwise the Means may be adjusted so as to have the average 100 (e.g. See Exercise VI, 8)

There is a simpler method for measuring the seasonal variations by taking the averages, which can be used when the general trend is fairly steady or has only a slight upward or downward slope otherwise adjustment has to be made for the Trend. The simple average method may be described as follows. An average value is obtained for each month and then a final average of all the monthly averages dividing by 12. By subtracting this mean of means, from the average figures for each month the seasonal Variations for each month are obtained (See Exercise VI, 7). At least three or preferably more years figures should be taken.

Besides the methods explained above, the methods of Link Relatives and 'Ratio to trend' are used which are rather complicated. The ratio to trend method measures the seasonal Variation and in addition the combined cyclical and residual Variations and depends on fitting a trend line to the data.

The Link Relative method, is based on 'link Relatives' in which we express the value for each month as a percentage of the previous month. The resulting percentages are called link relatives. Median is used as the average.

Exercise VI

1 Draw a freehand Trend for the following time series

1910	1911	1912	1913	1914	1915
810	890	780	784	846	775
1916	1917	1918	1919	1920	1921
816	820	875	750	807	750
1922	1923	1924	1925	1926	1927
36	807	735	783	780	760
1928					
720					

2 Draw the graph for the data in Q 1 and also the graph of three years moving Average

3 Draw the Trend by the semi average method from the following data

	1914	1915	1916	1917	1918	1919
Values	160	18	25.3	35.3	46.6	35.2
1920	1921	1922	1923	1924	1925	
44.6	50.9	53.6	64.5	70	79	
1926	1927	1928	1929	1930	1931,	
89.5	97.2	105.92	119	119.62	114.5	

Hint—Take up to 1922 first half with 1918 as middle year and find the Average Similarly for the other half with 1927 as middle year

4 Given the Index Number of food prices in the Punjab (1873—82—100)

Years	1861	1862	1863	1864	1865	1866	1867	1868
	139	67	59	71	83	83	94	126

(B Com 1945)

CHAPTER VIII

METHOD OF LEAST SQUARES, CURVE FITTING AND TRENDS

Curve fitting is an important subject from both theoretical and practical point of view. It is the representation of relationship between two variables by simple algebraic expressions. The chief method for fitting of curves to a given data is by means of the *least square method*. According to this method, we suppose the curve best fitted to be of the form

$$y = a + bx + cx^2 + dx^3 + ex^4 + \dots$$

If a straight line is to be fitted the equation takes the form $y = a + bx$ (two unknowns a and b)

For a second degree curve or second order parabola the equation takes the form $y = a + bx + cx^2$ (three unknown a , b and c)

For a third degree curve (a third order parabola) the

equation takes the form $y = a + bx + cx^2 + dx^3$ (four unknowns a, b, c and d) and so on

General procedure —

(a) Write down the type of the equation to be fitted and substitute the values of x and the corresponding y in the equation

(b) Form Normal equations for each unknown. The Normal equation for the unknown ' a ' is obtained by multiplying the equations by the coefficient of ' a ' and adding. The sum will be

$$(1) \sum y = na + b\sum x \text{ for a straight line.}$$

$$(2) \sum y = na + b\sum x + c\sum x^2 \text{ for a second degree curve}$$

$$(3) \sum y = na + b\sum x + c\sum x^2 + d\sum x^3 \text{ for a third degree curve}$$

where n is the number of items.

(c) Form Normal equation for the unknown b by multiplying the equations by the coefficient of b (which is x) and adding. The sum will be

$$(1') \sum xy = a\sum x + b\sum x^2 \text{ for a straight line.}$$

$$(2') \sum xy = a\sum x + b\sum x^2 + c\sum x^3 \text{ for a second degree curve}$$

$$(3') \sum xy = a\sum x + b\sum x^2 + c\sum x^3 + d\sum x^4 \text{ for a third degree curve}$$

curve

(d) Form Normal equations for the unknown c , by multiplying the equation by the coefficient of c (which is x^2) and adding. The sum will be

$$(2'') \sum yx^2 = a\sum x^2 + b\sum x^3 + c\sum x^4 \text{ for second degree curve.}$$

$$(3'') \sum yx^3 = a\sum x^3 + b\sum x^4 + c\sum x^5 + d\sum x^6 \text{ for third degree curve}$$

curve

(e) Form Normal equation for d by multiplying the equations by the coefficient of d (x^5, x^5) and add. We get

$$(3''') \quad \sum yx^5 = a \sum x^5 + b \sum x^6 + c \sum x^7 + d \sum x^8.$$

In general, the set of Normal Equations, for the curve

$$y = a_0 + a_1x + a_2x^2 + \dots + a_kx^k, \text{ are}$$

$$\sum y = a_0n + a_1\sum x + \dots + a_k\sum x^k$$

$$\sum xy = a_0\sum x + a_1\sum x^2 + \dots + a_{k+1}\sum x^{k+1}$$

$$\sum yx^2 = a_0\sum x^2 + a_1\sum x^3 + \dots + a_{k+2}\sum x^{k+2}$$

$$\sum yx^k = a_0\sum x^k + a_1\sum x^{k+1} + \dots + a_{k+2k}\sum x^{2k}$$

The number of Normal Equations will be the same as the number of the unknowns. Solving these equations simultaneously we get the values of the unknowns. These will be the most plausible or most possible values for these unknown quantities satisfying the set of equations obtained by substituting the various values of x and y . Such equations are known as the equations of observation. Putting the values of the unknowns in the equation, to be fitted, we get the required equation which represents the curve fitted to the data.

When the number of Normal equation is more other methods such as of (1) Determinants, (2) Normal equation coefficients, (3) Gauss's method, (4) Least squares method may be used. The Normal equations for a line from the general procedure are (1) and (1') for a straight line, (2) 2', 2'', for a second degree curve, (3) 3', 3'', 3''' which can be easily solved simultaneously. When we solved the equations for a , b , c and d , put the values in the respective equations to get the best fitted curve.

To fit a straight line to the given values of x and y

x	y	xy			
1	3	3			
2	4	8			
3	6	18			
4	5	20			
5	10	50			
6	9	54			
7	10	70			
8	12	96			
9	11	99	8		
Sum of Σ		45	70	418	28

The equations of observations are obtained by putting the value of x and y in $y = a + bx$, they will be,

$3 = a + b$, $4 = a + 2b$ and so on. Items here are 9, so

The Normal Equations are $\Sigma y = na + b \Sigma x$,

$$70 = 9a + 45b$$

$$\Sigma xy = a \Sigma x + b \Sigma x^2 = 418 = 45a + 285b$$

Solving these two equations, we get the most plausible values of a and b as $a = 2.11$, $b = 1.13$. The equation to

own on the graph paper. In this way the parabola of second order and third order or any other curve can be best fitted after forming the Normal equations and solving them.

Trend and the curve fitting

The Method of least square is applicable for the determination of the Trend. In a Time Series, where the period is given and equi spaced values corresponding to the periods are represented by y , the Time, years etc., are assigned numbers 0, 1, 2, 3, 4, 5, 6, 7, and they are taken as x . The starting year to which the number 0 is assigned, is known as the Origin Year. Here n will denote the total number of years. The rest of the process is the same as explained above. Form Normal equations and solve them the usual way. If the best fit is a line, this will be a linear trend otherwise non-linear Trend. The line is also called the Least Square line. The straight line trend does not satisfactorily describe the trend of data which have a varying rate of growth. In such cases a parabola may be fitted.

The trend values (y) for the various years may be obtained by substituting the appropriate values of x from the numbers 0, 1, 2, assigned to each year, in the equations obtained for the trend. These can be plotted on the graph paper to draw the curve.

Short method for trends—If the number of years is odd, take the middle year as origin year and assign 0 to it.

years and 1, 2, 3 to the succeeding years, so that will be zero. Thus if the years are 1919, 1920, 1921, 1922, 1923, the middle year is $1921=0$, the preceding years 1919, 1920 will be $-1, -2$ and the succeeding years 1922, 1923 will be 1, 2 so that $\sum x=0$. In this way, the working is simplified, and the simplified Normal equations will be $\sum y = na$, and $\sum xy = b\sum x^2$ for a linear trend. Similarly for the parabolas. Of course the origin year will be the middle year and not the year of start as in the general case.

For even number of years, the middle term presents some difficulty. To make $\sum x=0$ say for a series of six years 1926, 1927, 1928, 1929, 1930, 1931, take two middle terms (1928 and 1929) as -5 and $+5$ and the other years as with a difference of 1: $-7.5, -6.5, -5.5, -4.5, -3.5, -2.5, -1.5, -0.5, 0.5, 1.5, 2.5, 3.5, 4.5, 5.5, 6.5, 7.5$, so that the sum is zero the origin being middle of two centre years. If decimals are to be avoided, a trend equation may be obtained by working in terms of half years, doubling the above assigned values and taking them for x numbers. The rest of the process is the same as explained above.

The constant ' a ' in the trend equation defines the trend value in the year taken as origin. If the annual data employed in the fitting process are averages of twelve monthly values, ' a ', measures the trend value for a month centring at the middle of the year covered by the annual values.

Graphs of time series on logarithmic scale have been

nding to a time series are used substitute (logy) in
ace of y in the equations and proceed in the same way
obtain the logarithmic trend

curves of the type $y = ax^b$ and $y = ab^x$

Occasionally neither the straight line nor the para-
bola will describe the trend of a particular series. The

curves of the type $y = ax^b$ and $y = ab^x$ may describe the

trends. The equation $y = ax^b$ reduces to $\log y = \log a + b \log x$. The Normal equations are formed by changing
into $\log y$ and x into $\log x$. The remaining process is the
same as in the case of a straight line trend. The
equations are to be solved for $\log a$ and b . Similarly

an exponential curve $y = ab^x$ reduces to $\log y = \log a + x \log b$ and can be likewise treated. There are some expon-
ential curves of importance for trend purposes. One of
the more important curve is known as Gompertz curve,

whose equation is $y = ab^{\frac{x}{e}}$. Its use in the analysis of
economic statistics has been based upon the ground that
there is a general law of growth characteristic of popu-
lation increase and that this kind of growth is found in
industries whose products are a direct function of the growth
population.

A somewhat similar curve of growth is the logistic
curve employed in forecasting population growth. A form
of this curve adapted as a measure of trend is given by

$$\frac{1}{1 + e^{-\frac{x}{a}}}$$

Exercise VII

I.—Fit a straight line to the following data.

x	20	5	10	15	10
y	24	15	17	22	12

$$\text{Ans. } y = 73x + 9.23$$

What is the line if one more item is added

x	24	Ans.
y	30	

$$\text{Ans. } y = 86x + 7.96$$

II.— x	7,	6,	7,	8,	8,	8,	9,	9,	10
y	5,	5,	4,	3,	4,	5,	4,	3,	3

$$\text{Ans. } y = -5x + 8.$$

III.—Fit a straight line and parabolas of the second and third orders to the following

x	0,	1,	2,	3,	4
y	1,	1.8,	1.3,	2.5,	6.3

$$\text{Ans. } 2.58 + 1.13x$$

$$y = 1.4 + 1.13x + 5x^2$$

$$y = 1.4 + 0.25x + .5x^2 + 32x^3$$

IV.— x	y	x	y
63	40	3193	290
223	1565	3238	259
755	188	1228	231
165	78	2695	255
1535	315		

Fit a quadratic parabola (i.e. of second order).

$$\text{Ans. } y = 48.33 + .238x - .00005x^2.$$

V—Fit a parabola of second degree to the following data and draw it

Years	y	Years	y
1910	81	1930	134
1915	84	1935	148
1920	88	1940	170
1925	104		

Upon the hypothesis that y continues to increase during the next decade according to this trend, extrapolate or estimate the number for 1950

Hint—The years are equispaced with a difference of 5, so x may also be taken as 0, 5, 10, 30

with a difference of 5. The middle year may be taken as origin

$$\text{Ans } y = 78.6 + 68x + 0.82x^2$$

For 1950 (when $x=40$) $y=237$ nearly.

VI—Find the most probable values of x and y from
 $x+y=3.01$, $2x-y=0.3$, $x+3y=7.02$, $3x+y=4.97$

(M A, 1942)

Ans 99 and 2.08

VII—Fit a second degree parabola to the data and plot it

x	1	2	3	4	5	6	7	8	9
y	2	6	7	8	10	11	11	10	9

$$\text{Ans } y = -929 + 352x - 267x^2$$

VIII—Given the data

Year	1932	1933	1934	1935	1936	1937	1938	1939
x	1	2	3	4	5	6	7	8
	722.4	713.0	763.7	770.0	901.1	901.5		1.3

Fit a curve of the type, $y = a^x b^x$

$$\text{Ans. } \log y = 2.75645 + .03044x$$

(With origin 1931).

$$\text{Or } y = 570.8(1.0726)^x$$

IX.—In the following data, S denotes son's stature, and F, father's, in inches

S	65.7	66.8	67.2	69.3	69.8	70.5	70.9
F	62	64	65	69	70	71	72

Fit the relation $S = a + bF$, by determining most probable values of a and b

(Aligarh, 1943 M A)

$$\text{Ans. } S = 33.351 + .522F.$$

X.—Given the data for (1920—1938)

805, 895, 785, 784, 846, 775, 816, 823, 874, 750, 807, 750, 736, 807, 734, 785, 784, 765, 715.

Fit a st line with (1919 as origin)

$$\text{Ans. } y = 839.4 - 4.8x$$

Hint.—Take values for years 1920, 1911 1938 as 1, 2, 3, 4, 5, ...

XI.—Given Annual Production of wheat (1926—1940) in millions of maunds in a country, find the linear trend with (1) 1926 as origin, (2) 1933 as origin

3 = 111, 143, 143, 134, 138, 55, 74, 129, 150, 140, 145, 160, 210, 225, 229

$$\text{Ans. (1) } y = 95.15 + 7.2x. \quad (2) y = 145.753 + 7.23x$$

Is the production trend figure the same for 1933 by the two methods?

Ans. Yes. — 145.753 = 145.753

XII — Fit a straight line to the data for 1926—1941

900 1022, 1040, 1080, 1111, 1137, 1176, 1260, 1363, 1420, 1484, 1590 1727, 1828, 1890, 1895

$y = 1370.12 + 34.2x'$ where x' is in $\frac{1}{2}$ year (double of $-7.5, -6.5, -5.5, \dots, 7.5$)

XIII — For data of Exports in crores for a country, (1925—1940), fit a second degree parabola with 1925 as origin

26, 85, 10, 133, 9, 153, 127, 138, 20, 283, 306, 425, 443, 53, 62 and 656.

Find the trend values for 1935 and deviation of the actual from the trend

Ans $y = 7.21 - 51x + 304x^2 : 32.53$ nearly.

Hint — Actual value for 1935 = 306 and deviation from trend = $306 - 32.53 = -1.93$

XIV — Data of Index Numbers (1915—1927)

114, 110 100 110, 100, 125, 115, 125, 135, 120, 115, 125, 110

Determine the ordinates for the trend of the cubic parabola (1914 as origin)

Ans 112, 109, 107, 106, 109, 114, 118, 123, 126, 127, 125, 120 and 110 (nearly).

XV — Fit a curve to the population of India of the form

$y = ab^x$ given in crores,

1871	26'16	1901	29'64
1881	26'68	1911	31'53
1891	29'23	1921	31'1

XVI.—Find the most plausible values of x , y and z from
 $x - y + 2z = 3$, $3x + 2y - 5z = 5$,

$$4x + y + 4z = 21, -x + 3y + 3z = 14.$$

(M.A. 1943). Ans. 2.5, 3.5, 1.9

XVII —Form normal equations and solve

$$x + 2y + z = 1, 2x + y + z = 4, -x + y + 2z = 3, 4x + 2y - 5z = -7.$$

(M.A. 1945) Ans. 1.16, - .74, 2.08.

XVIII —Explain what is meant by (a) Secular Trend,
 (b) Seasonal Variations Show how the method of curve
 fitting is used in the measurement of a Trend

(Indian Audit & Acc'ts. Exam 1945)

XIX —A manual experiment on paddy gave the following results

Dose of measure in lbs (x) 0 200 400 600

Yield per acre in lbs (y) 1544 1898 2133, 2327

Plot the relationship between the two and use the least square method to fit a parabola of the second degree to represent it

Ans. $y = 1547.9 + 378.4x - 40x^2$ (C. St & M.A. 1945)

CHAPTER IX

CORRELATION AND REGRESSION

So far we have been dealing with the problems which arise from variation in a single variable. We will now deal with the simultaneous variation of two or more variables. Methods of measuring the degree of relationship existing between two variables have been chiefly developed by Galton and Karl Pearson. It is often desirable to observe and measure the relationship (association), between two or more statistical series. For instance it may be desirable to know whether there is relationship between changes in the cost of living and changes in wages, the amount of electrical current passed through a solution and the amount of substance deposited by electrochemical reaction, prices of food grains and rainfall,

When two quantities are so related that the fluctuations in the one are in sympathy with fluctuations in the other, so that an increase or decrease of the one is found in connection with increase or decrease of the other, (or inversely), the two quantities are said to be correlated and the correlation is said to be simple in case of two variables.

Correlation may be direct or positive, if an increase, or decrease in the values of one set is associated with increase or decrease of the other set. If the increase or decrease is associated with decrease or increase of the other, correlation is said to be inverse or negative.

Let there be two series x and y to be represented graphically.

Take the items in x series along the axis of x , and the corresponding items in y series along the y -axis. The diagram so formed will be a dotted one and scattered, showing some relationship. Such a diagram is called a Scattered Diagram.

Co-efficient of Correlation — The numerical measure of correlation is called the coefficient of correlation, denoted by r , which lies between 1 and -1 . If $r=1$, correlation is said to be perfect. If $r=0$, there is no correlation at all. Correlation is said to be Null.

The following formulae are used to find the coefficient of correlation.

1. Ungrouped data, for x and y series

$$r = \frac{\sum d_x d_y}{n \sigma_x \sigma_y}$$

where d_x stands for deviations of the items in x from the arithmetic mean of the x series

d_y stands for deviations of the items in y series, the arithmetic mean of y series

σ_x the standard deviation for x series,

σ_y the standard deviation for y series

n the number of items

The formula is known 'Product Moment' formula to Pearson

It gives a measure of the intensity of the association of the pairs of observations

Suppose it is required to find relationship between the x and y series given by —

x	y	d_x	d_y	$d_x d_y$	d_x^2	d_y^2
28	27	-2	2	-4	4	4
27	20	-3	-5	15	9	25
28	22	-2	-3	6	4	9
23	18	-7	-7	49	49	49
29	21	-1	-4	4	1	16
30	29	0	0	0	0	16
31	27	1	2	2	1	4
36	29	6	4	24	36	16
35	28	5	3	15	25	9
33	29	3	4	12	9	16
<hr/>						
Mean = 30				123	138	164

Means of the two series are 30 and 25

$$\sum d_x d_y = 123$$

$$\sigma_x = \sqrt{\frac{\sum d_x^2}{n}} = \sqrt{\frac{138}{10}} = 3.715$$

$$\sigma_y = \sqrt{\frac{\sum d_y^2}{n}} = \sqrt{\frac{164}{10}} = 4.05$$

$$\therefore \text{Coefficient of correlation } r = \frac{123}{10 \times 3.715 \times 4.05} = .817$$

Since r must be between 1 and -1, it is evident that we have a fairly high degree of correlation

2. Instead of finding the arithmetic mean we can short cut method by taking the Provisional mean and the formula

$$r = \frac{\frac{\sum D_x D_y}{n} - \frac{\sum D_x}{n} \cdot \frac{\sum D_y}{n}}{\sigma_x \sigma_y}$$

where n is the number of items and D_x , D_y are the deviations of the respective items from that Provisional Mean.

3 *Correlation for grouped data* — When the x series and y series are given as frequency distributions, they can be placed in the form of a Table with one series on horizontal side and the other vertically as shown in the following example. The table is called 'Correlation Table'. The formula for a correlation table is

$$r = \frac{\frac{\sum f D_x D_y}{n} - \frac{\sum f D_x}{n} \cdot \frac{\sum f D_y}{n}}{\sigma_x \sigma_y}$$

where D_x denotes the deviations of the Central Values from

the Provisional Mean in x series.

D_y denotes the deviations of the Central Values from

the Provisional value in y series.

f denotes the corresponding frequencies.

n denotes the total number of frequencies.

The whole working will be clear from the following example -

Example 2—Correlation Table showing age in years of the students and the Marks obtained

<i>y</i> Series Marks.	<i>D_x</i>						<i>Total of Frequencies for y Series</i>	<i>D_y</i>	
	<i>Age in years</i>								
	$\frac{x}{\text{CentralValues}}$	16—18 17	18—20 19	20—22 21	22—24 23				
10—20	15	2	1	1		4	15—35	—20	—15
20—30	25	3	2	3	2	10	—10	—5	—15
30—40	35	3	4	5	6	18	0	—5	—15
40—50	45	2	2	3	4	11	10	—15	—15
50—60	55		1	2	2	5	20	—15	—15
60—70	65		1	2	1	4	30	—15	—15
Total of frequencies for <i>x</i> Series		10	11	16	15	52			

We are given two frequency distributions denoted by x series and y series, x series being horizontal Column D_y gives the deviations from the Provisional Mean 35, (corresponding to Maximum Frequency 18) of the Central Values of y series

D_x gives the Deviation of the Central Values of x series from the Provisional Mean 21 (corresponding to the maximum frequency 16)

$$\Sigma f D_x D_y = 2 \times -4 \times -20 + 3 \times -4 \times -10 + 3 \times -4 \times 0 + 2 \times -4 \times 10 + 1 \times 40 + 2 \times 20 + 0 - 2 \times 20 + 1 \times -40 + 1 \times -60 + 0 + 0 - 2 \times 20 + 0 + 4 \times 20 + 2 \times 40 + 1 \times 60 = 320$$

$$\Sigma f D_x = 10 \times -4 + 11 \times -2 + 0 + 15 \times 2 = -32$$

$$\Sigma f D_y = 150$$

$$\sigma_x = \sqrt{\frac{\Sigma f (D_x)^2}{n} - \left(\frac{\Sigma f D_x}{n} \right)^2} = \sqrt{\frac{12704}{52}}$$

$$\frac{32}{32} \frac{64}{96}$$

$$\sigma_y = \sqrt{\frac{61100}{52}}$$

∴ Co-efficient of Correlation

$$r = \frac{\frac{320}{52} - \left(-\frac{32}{52} \right) \left(\frac{150}{52} \right)}{\frac{32}{52} \times \sqrt{12704} \times \frac{150}{52} \times \sqrt{46110}} = .28$$

If the arithmetic mean is to be used for calculation then

$$r = \frac{\Sigma d_x d_y}{n \sigma_x \sigma_y} \checkmark$$

Correlation of Time Series

Correlation for long term fluctuations—When it is desired to measure the correlation in long term fluctuations, for economic and commercial data, Pearson's formulae

is used viz. $r = \frac{\sum d_x d_y}{n \sigma_x \sigma_y}$ one series say x series is called

'Subject' and the other series or y Series the Relative. The subject is applied to the more important series.

Correlation for short term fluctuations

To study relationship existing in short term fluctuations instead of using the deviations of the items of the Relative and the Subject, from the arithmetic average, we calculate the deviations from the Trend.

The moving average of the Index Numbers of the two factors is calculated and the deviations of such figures from the moving average of the Indices will be the measure of standard deviation in each of the cases.

The rest of the method of calculation is the same as shown above.

Coefficient of Concurrent or Concomitant Deviations

Various difficulties arise when using Pearson's formula in connection with time series subject to short term fluctuations and a coefficient of correlation called 'coefficient of concurrent deviation' exists which gives a simple and easily calculated co-efficient

If it is required to know only whether two series move in the same direction or if one series moves in the opposite direction from the other, the concurrent or concomitant deviations may be used as a basis for measurement. Concurrent deviations are those deviations that are in the same direction for corresponding items in each series.

Subject		Relative		
	Out put of coal Tons.	Deviations from preceding months or 'First Differ ences.	Unemp loyed in coal Industry 000's	First Differ ences
January	18.5		260	
February	19.2	+ 7	265	+5
March	19.3	+ 1	261	-4
April	18.5	-	274	+
May	17.2	-	292	+
June	15.9	-	357	+
July	15.1	-	330	-
August	16.6	+	306	-
September	17.9	+	258	-
October	17.6	-	280	+
November	18.2	+	250	-
December	19.3	+	225	-

The formula for coefficient of concurrent deviations

$$= \pm \sqrt{\pm \frac{2c-n}{n}}$$

where n is the number of items, c = number of concurrent deviations

If the expression $2c-n$ is negative, we must insert a minus before and after $\sqrt{\quad}$. Hence the general expression $\pm \sqrt{\pm}$ is done to avoid an expression containing the root of a negative quantity.

In the above table, $n=11$, and $c=2$ (as there are two concurrent cases, in February and July)

* Co efficient of concurrent deviation

$$= \pm \sqrt{\pm \frac{2 \times 2 - 11}{11}}$$

$$= - \sqrt{-(-\frac{7}{11})} = - \sqrt{636} = - 8$$

This co efficient is influenced only by the direction of the deviation and not by the magnitude

This is of no use for long term fluctuations Its principal value is that it indicates the direction of the movements of one series in relation to the other

Ratio of Variation and line of Regression—There may exist almost perfect correlation when two series move, but the proportional movements may be very different. In many cases a measure of this proportional variation can be usefully employed, and the proportional variation for both series having been obtained, comparison of the two by means of a ratio gives us the ratio of variation

When the movements are regular, the Ratio of variation is obtained as follows —

Take the deviation of the relative items from the mean at each date and divide it by the corresponding deviation of the subject. Add the quotients so obtained and divide by the number of quotients

Since economic and social series are irregular, it has been found it practice that the Ratio of variation is best determined by graphical method as follows —

Plot the Index Numbers (or first convert if index numbers are not given) with subject on the vertical and the

of points widely scattered. A line is drawn through the scattered points most nearly approximating the general trend of the points plotted, so that approximately an equal number of points lie on each side of the line. If perfect correlation exists, the line plotted will be perfectly straight, otherwise a well defined and regular curve.

If the line points downward to the left, then correlation is direct and *vice-versa*, if no well defined tendency is exhibited, no correlation exists.

The graph is known as 'Galton graph'. If in this graph, both the subject and the Relative change by equal percentages, then the ratio of variation is equal to unity (one) and the line drawn through the plotted points will be a line at an angle of 45° to the horizontal and such a line represents a line of equal variation or equal proportional variation. When the Relative shows a tendency to change less than the subject, the line will be at an angle less than 45° to the vertical (more than 45° to the horizontal).

If the Relative changes more proportionally than subject, the line will be at an angle less than 45° to horizontal.

This line is known as the regression line. The nearer this regression line approaches the vertical, the slighter the degree of correlation. The larger the number of points plotted the more reliable the result will be.

The Galton graph, drawn, in the annexed diagram shows that the regression line is at an angle greater than 45° that is the proportional changes in share prices are

less than the proportional changes in the volume of production, or share prices fluctuate less widely than does the volume of production. A numerical value is obtained by measuring the angle that the regression line makes with the vertical. The ratio of the average variation of the Relative to the average variation of the Subject is represented by the tangent of the angle.

Or Ratio of variation = $\tan XYZ$, where XY is the vertical.

or $= \frac{AX}{XY}$, when A is a point where a perpendicular from a point on the vertical cuts the regression line.

Equations of the lines of Regression—Mathematically equations of the lines of the regression are

(1) $y - \bar{y} = \frac{r\sigma_y}{\sigma_x} (x - \bar{x})$ where \bar{x} and \bar{y} denote the means of x and y series.

Changing the origin this can be simply written as

$$y = \frac{r\sigma_y}{\sigma_x} x$$

This expresses the most probable value

of y associated with a given x and it is the regression line of y on x .

From example 1, $y = 817 \times \frac{4.05x}{3.715} = 891x$

$\frac{r\sigma_y}{\sigma_x}$ is called the regression coefficient. 891 is regression coefficient here.

The above regression equation gives the regression of

The Regression equation,

Galton Graph

Ratio of variation - $\tan \angle x_1 y_1 z$

$x = r \frac{\sigma_x}{\sigma_y} y$ gives regression of x on y , $r \frac{\sigma_x}{\sigma_y}$ being the

co-efficient of regression. The regression co-efficients denote the slopes of the regression lines.

Significance of the co-efficient of correlation — Probable and standard error of r . To test whether the calculated co-efficient of correlation is significant or not the standard error or the probable error (P.E.) can be used. Standard error $S.E. = \frac{1-r^2}{\sqrt{n}}$

$P.E. = \frac{6745(1-r^2)}{\sqrt{n}} = 6745 \text{ standard error}$ Correlation will be $r \pm P.E.$

If r is less than P.E. correlation does not exist.
Correlation may be taken as good.

If r is more than P.E. several times (at least 3)

If r is more than 6 times P.E. correlation is definitely good.

Significance of the correlation co-efficient is also dealt with later on in Chapter XI.

Exercise VIII

1 — Compute the co-efficient of correlation for the following —

x	y	x	y
1	3	4	5
2	1	5	4
3	2		

Ans 6

II.—	x	y	x	y
	7.2	17.7	3.8	17.8
	11.7	21.1	5.1	18.
	8.7	19.2	8.6	19.7
	15.2	22.5		

Ans. '96.

III.—	x , 600	-500,	-400,	-200,	600,
	y , -1800,	1500,	1200,	600,	-1800,
	700,	-300,	-500.		
	-2100,	900,	1500		

Ans -1 (perfect negative correlation).

IV —Supply	400,	200,	700,	100,	500,	300
Demand	50,	60,	20,	70,	40,	30,
	600					

10

Ans -'86.

V —City	Population (thousands)	Accident rate per million.
A	10	32
B	20	20
C	30	24
D	40	36
E	50	40
F	60	28
G	70	48
H	80	44

Ans '71.

VI —Find r , between sanitation and infant mortality for the indices of the eight cities

Sanitation	100,	86,	91,	108,	111,
Infant mortality	98,	108,	104,	98,	94,
	112,	105,	87.		
	90,	100,	108.		

VIII — Compute r , given.

x ,	22,	27,	12,	21,	21,	27,	23,	17,	25,	1
y ,	32,	27,	19,	30,	26,	26,	25,	22,	23,	2
	16,	20,	37,	33,	18,	24,	22,	17,	32,	3
	24,	28,	29,	25,	20,	26,	17,	16,	27,	25
	26,	27,	26,	21,						
	17,	20,	26,	17						

Ans. 0.3

VIII — What is the correlation co-efficient after adjusting the Probable Error in the following? Is it significant?

Capital in hundreds	10,	20,	30,	40,	50,	60,	70,
of Rupees (Subject)							
Profits in hundreds	2,	4,	8,	5,	10,	15,	14,
(Relative)							

80, 90, 100

20, 22, 30

Ans. $.9618 \pm .01598$ Y

IX.—Draw the Galton graph from the following and show the Ratio of Variation between the following for eight years

Year	Subject Tense of Thousands	Relative in millions of Rs
1	79	49
2	52	40
3	33	25
4	55	35
5	46	35
6	62	34
7	31	34
8	34	28

Hint.—Form the Index Numbers, by taking the av

variation = $\frac{52}{70} = .74$ approx. The complement of this fraction

$-.74 = .26$ is called the Ratio of Regression

X —	Subject Sales, 00 Rs. 50	Relative Expenses 00 11	Subject Sales, 00. Rs 65	Relative Expenses 00. 15
	50	13	65	15
	55	14	60	14
	60	16	60	13
	65	16	50	13

Find the Standard Error and the Probable Error Is the relation significant ?

$r = .79$, P E = 08, S E = 12 Significant.

XI —	Years	(A) First Differences.	(B) First Differences.
	1	-140	8
	2	739	-2
	3	-620	18
	4	-5486	23
	5	1801	25
	6	385	7.2
	7	3488	-8.4
	8	2576	-4.4
	9	1873	-7.3
	10	-5020	8.7

What is the co-efficient of concurrent Deviation ?

What would have happened if all the first differences in the two columns had the same sign ?

Ans — .77 perfect correlation.

XII.—	Mean annual Birth rate per 1000 of population.	Mean annual \bar{C} Rate per 1000 population
	35.3	20.8
	33.5	19.4
	31.4	18.9
	30.5	18.7
	29.3	17.7
	28.2	16.0
	26.3	14.7
	23.6	14.3
	20.1	14.4
	19.9	12.2
	16.7	12.1

Find r , Ans.

XIII.—Find the Regression co-efficients and lines of Regression for Q. VII.

$$\text{Sol. } x = .537 \times \frac{6.18}{5.36} y, \text{ and } y = 537 \times \frac{5.36}{6.18} x$$

XIV.—	Density of population per square Mile.	(1)	(2)
	163	13.3	4.3
	165	42.5	0.0
	380	38.2	2.1
	431	38.8	1.3
	487	16	1.2
	440	22.4	1.2
	594	15.5	3.1
	710	20.2	1.6
	791	28.2	3.0
	2157	13.5	3.6

Find correlation between :—

Population and (1)	Ans.
Population and (2)	A

XV — Calculate the coefficient of correlation for the following data giving the prices in ten markets of commodities A and B

A	61	72	73	63	84	80	66	76	74	72
B	40	52	49	43	61	58	42	58	44	45

(M A 1943) Ans 88

XVI — Find the lines of regression for the correlation table connecting Age and Marks given in the solved example 2

(M A Aligarh 1943)

Sol — See solved example giving values of σ_x , σ_y and r and then put these in the equations

XVII — Calculate the coefficient of correlation between the prices of standard wheat and rice from the distribution giving below showing the prices in the same day in 31 markets in the Province

Prices in annas per maund of wheat

		60	64	68	72	76	f_y

	12													
Avg. 145 (range)														

Ans. .45 (nearly)

XX — (1) Define the product moment co-efficient of correlation r and prove that $-r \leq r \leq 1$

(2) Obtain the expression for r and the equation of the lines of regression

India Audit Accounts 1943 and M. A. (Mathematics 1945)

XXI — The following marks have been obtained by a class of students in statistics (out of 100)

Paper I 80, 45, 55, 56 58, 60, 65, 68, 70, 75, 85

II 82, 56, 50, 48 60, 62, 64, 65, 70, 74, 90

Compute the co-efficient of correlation for the above data. Find the lines of regression and examine the relationship

(Indian Audit & Accounts Examination 1945) $r = .92$

XXII — The following table gives the value of exports of raw cotton from India and the value of the imports of manufactured cotton goods in India for six years

<i>Exports of raw cotton</i> <i>In crores of rupees</i>	<i>Imports of manufactured</i> <i>goods</i>
45	50
58	53
55	58
89	65
98	76
66	58

Calculate the co-efficient of correlation between the value of the exports and of the imports

Test the significance of the co-efficient

Ans $r = .94$ good (*B. Com. 1945*)

XXIII.—Calculate the co-efficient of correlation for short time oscillations from the following indices (1930—1944) taking a five years moving average.

x	116, 114, 111, 91, 93, 95, 92, 93, 96, 102, 107,
y	78, 84, 93, 117, 97, 102, 108, 105, 96, 77, 68,
	104, 98, 100, 108,
	77, 93, 89, 83.

Hint.—Take Moving Average for 5 years, takes deviations from the moving average of the corresponding indices and apply the formula. $n=11$ *Ans.*—'.9 (*appr.*)

XXIV —Given marks as

Roll No.	1	2	3	4	5	6	7	8	9	10	11	12
Mathematics Paper	36	56	41	46	59	46	65	31	63	41	70	36

CHAPTER X

MOMENTS AND NORMAL DISTRIBUTIONS

Moments play an important part as a method of comparison and in testing normality symmetry and skewness of a distribution. Moments are defined about the arithmetic mean and about an arbitrary mean (or origin). Moments about arithmetic mean M are defined by the formula for r th moment as (1) for ungrouped data $\mu_r = \frac{1}{n} \sum (x - M)^r$ or $\frac{1}{n} \sum d^r$ where n is the number of items in the series $x_1, x_2, x_3, \dots, x_n$. Thus

the first four Moments about the mean are

$$\mu_1 = 0, \mu_2 = \frac{1}{n} \sum (x-M)^2 = \frac{1}{n} \sum (d^2)$$

which means the variance which have been studied

in Dispersion, $\mu_3 = \frac{1}{n} \sum (d^3)$, $\mu_4 = \frac{1}{n} \sum (d^4)$. For grouped

the r th moment about the mean is given by $\mu_r = \frac{1}{n} \sum f$

where n is the total number of frequencies and d the deviation of the central values from the arithmetic mean.

Moments about any provisional mean are given

$V_r = \frac{1}{n} \sum f(D)^r$ where D denotes deviations from the provisional mean, of the central values

Moments about the mean and about any provisional origin are connected* as follows —

$$\mu_1 = 0, \mu_2 = V_2 - V_1^2, \mu_3 = V_3 - 3V_1V_2 + 2V_1^3$$

$$\mu_4 = V_4 - 4V_1V_3 + 6V_1^2V_2 - 3V_1^4.$$

*For Math. Proofs see Appendix.

In practice generally we need the first four moments to be calculated as follows — Take the central values of the class intervals and then deviations (D) of these from the provisional mean (preferably the class interval having the maximum frequency). Multiply the deviations by corresponding frequencies and add. This will give $\sum fD$. Similarly find $\sum fD^2$, $\sum fD^3$ and $\sum fD^4$ to get V_2 , V_3 and V_4 . Put these values in μ_2 , μ_3 and μ_4 to get the Moments about the Mean.

and corrections (Sheppard's) may be applied for grouping and the adjusted moments are then given as $\mu_1=0$; $\mu_2=\sigma^2=V_2-V_1^2-i_2^2$, μ_3 remains unchanged and $\mu_4=V_4-4V_1V_3+6V_1^2V_2-3V_1^4-\frac{1}{2}\mu_2^2+\frac{7}{24}\sigma^4$ where i denotes class interval

Normal Distributions—In dealing with graphs on frequency distribution, a smoothed curve, a bell shaped curve has been drawn. This smoothed curve may be a continuous and perfectly symmetrical curve known as the Normal curve stretching to infinity at both ends (Figure next Chapter) and it is the curve representing Normal distributions.

To determine whether a given distribution is Normal, we have to determine some other statistical parameters known as α , β , γ define as —

$$\alpha_1 = \frac{\mu_1}{\sigma}, \alpha_2 = \frac{\mu_2}{\sigma^2} = 1, \alpha_3 = \frac{\mu_3}{\sigma^3} = \sqrt{\beta_1}$$

$$\gamma_1 = \frac{\mu_3}{\mu_2^{\frac{3}{2}}}$$

$$\alpha_4 = \frac{\mu_4}{\sigma^4} = \frac{\mu_4}{\mu_2^2} = \beta_2 = \gamma_2 + 3 \quad \beta_1 \text{ and } \beta_2$$

are the measure of Symmetry and Normality. If $\beta_1=0$ the distribution is symmetrical if α_4 or $\beta_2=3$, the distribution is Normal. The quantity α_4 measures a characteristic called 'Kurtosis' i.e., flatness of the curve, α_4-3 is called the Excess over the Normal distribution. If $\alpha_4 < 3$, the curves is said to be platykurtic (flat-topped and short-tailed) if greater than 3, then it is said to be leptokurtic. (Peaked more sharply and long-tailed).

For a normal curve $\beta_1=0$, $\beta_2=3$ & Excess, $E=0$.

Skewness can also be measured in terms of β_1 and β . For a large class of curves to which the moderately is a close approximation, the skewness is given by

$$\frac{\sqrt{\beta_1}}{2(5\beta_2 - 6\beta_1 - 9)}$$

Example.—Calculate the four Moments for the following distribution of wages after applying Sheppard's corrections

Weekly earnings, <i>x</i> Rs.	Men <i>f</i>	<i>D</i> from a Mean 10	<i>f D</i>
5	1	-5	-5
6	2	-4	-8
7	5	-3	-15
8	10	-2	-20
9	20	-1	-20
10 —	51	0	0
11	22	1	22
12	11	2	22
13	5	3	15
14	3	4	12
15	1	5	5
	131		8

Performing the calculations, we shall have

$$V_1 = \frac{\sum f D}{n} = \frac{8}{131} = .06,$$

$$V_2 = \frac{\sum f D^2}{n} = \frac{346}{131} = 2.64,$$

$$V_3 = \frac{\sum f D^3}{n} = \frac{74}{131} = 56,$$

$$V_4 = \frac{\sum f D^4}{n} = \frac{3718}{131} = 28.38$$

Hence, using the formula for μ_2 , μ_3 , and μ_4 in terms V_1 , V_2 after applying Sheppard's corrections, we have after calculation, $\mu_2 = V_2 - V_1^2 - \frac{1}{12} = 2.55$

$$\mu_3 = 57 - (3 \times 2.66 \times .06) + 2 \times (.06)^3 = .085$$

$$\mu_4 = 28.4 - (4 \times .06 \times .56) + 6 \times (.06)^2 \times 2.64$$

$$- 3(.06)^4 - \frac{1}{2}(2.56) + .029 = 27 \text{ nearly}$$

If we want to test the symmetry and normality, then find β_1 and β_2

$$\text{Now, } \beta_1 = \frac{(\mu_3)^2}{(\mu_2)^3} = .00036 \text{ (approx.)}$$

$$\beta_2 = \frac{27}{(2.55)^2} = 4 \text{ (approx.)} = \frac{\mu_4}{\mu_2^2}$$

Here $\beta_2 > 3$, so that the distribution is leptokurtic and not normal. As β_1 is very small, symmetry exists.

Exercise IX

1. Find the first four moments about the mean for the data in Q I and II.

x 1, 2, 3, 4, 5, 6, 7, 8, 9

f 1, 6, 13, 25, 30, 22, 9, 5, 2

Aligarh University M.A. 1942)

(Ans $\mu_2 = 2.478$, $\mu_3 = .679$, $\mu_4 = 18.35$

X.

II.—	30—40,	40—50,	50—60,	
	2	3	11	
	60—70,	70—80,	80—90,	90—100
	20	32	25	7

Find also β_1 & β_2

Ans 172, -1320, 94096,

$\beta_1 = 34$, $\beta_2 = 3.17$.

III—Compute the first four moments about an arbitrary origin from the following frequency distribution of heights in inches of adult Irishmen.

Height	59	60	61	62	63	64	65	66	67	68	69	70	71	72	73
Adults	1	0	2	2	7	15	33	58	73	62	40	25	15	10	3

(Punjab University M A 1942)

Ans. '341, 4 821, 4 468, 81'61

IV—Data from a fisheries investigation, x being the numbers of tail rays in 703 flounders Find α_1 and test for Normality

x	47,	48,	49,	50,	51,	52,	53,	54,
f	5,	2,	13,	23,	58,	96,	134,	127,
	55,	56,	57,	58,	59	60,	61	
	111,	74,	37,	16,	4,	2,	1	

(M.A 1942) 3'3, leptokurtic.

V—Calculate the first four moments about Mean of the distribution of Weights given by the following data after applying Sheppard's corrections.

Weights Seers, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77,

Men 2, 4, 14, 41, 83, 169, 394, 669, 990, 1223, 1329, 1230, 1063, 646, 392, 202, 79, 32, 16, 5, 2.

Ans. 5533, -'208, 134 409.

VI.—Find β_1 and β_2 , skewness and Kurtosis for Q. V.

Ans skewness = 006, leptokurtic $\beta_1 = 00015$ & $\beta_2 = 3.14$

VII — Given x in Annas 156, 159, 162, 165, 168,

Men · 3, 9, 26, 53, 89,

171, 174, 177, 180, 183, 186, 189, 192, 195, 198

146, 188, 181, 125, 92, 60, 22, 4, 1, 1

Find the moments about the Mean and α_3, α_4 .

Ans. 43.35, -9.77, 5508.56;

$\alpha_3 = -0.33$ · $\alpha_4 = 2.92$; (approximately Normal)

VIII.—Find the standard deviation, adjusted β_1 and β_2 (after Sheppard's correction) for Q VII and test for normality $\sigma = 6.5$; $\beta_1 = 0.012$ $\beta_2 = 2.93$ (approx. Normal)

IX — Find $\mu_2, \mu_3, \mu_4, \beta_1, \beta_2$ after Sheppard's correction for

x 3, 8, 13, 18, 23, 28, 33, 38, 43, 48, 53, 58, 53

f 5, 9, 28, 49, 58, 82, 87, 79, 50, 37, 21, 613

Ans 5.34, 0292, 76.1143,

β_1 & $\beta_2 = 0.0056, 2.663$

X.—Find moments after corrections for

x 59, 61, 63, 65, 67, 69, 71

f 1, 29, 48, 131, 102, 40, 13

Ans. 4.7, -89, 82.85.

XI.—Derive the expressions for moments about the Mean
terms of the moments about any arbitrary origin

Calculate the moments for the following —

Marks	20—30,	30—40,	40—50,	50—60,	60—70,	70—80
Frequency	6	28	96	75	56	30
					80—90,	90—100
					8	1
					M A (Math 7)	

$$\text{Ans } V_1 = -087, 1753, 3133 \text{ \& } 82333$$

XII — Calculate the first four moments, β_1 & β_2 and for symmetry and normality

XII — Weekly 15, 16, 17, 18, 19, 20, 21, 22
earnings

Labourers 8, 10, 15, 20, 25, 30, 40, 50

(C St 1945) Ans .

CHAPTER XI

ELEMENTS OF PROBABILITY, SAMPLING, TEST OF SIGNIFICANCE AND ANALYSIS OF VARIANCE

The theory of Probability plays a very important part not only in Statistics but in all sciences. Here we shall explain its meaning very briefly.

If an event can happen in m ways and fails in n ways and each of these $(m+n)$ ways are equally likely to occur, the probability of the happening of the event is $\frac{m}{m+n}$

and that of its failing is $\frac{n}{m+n} = q$

The sum of the probability of the success p failure q is $= 1$

When a coin is tossed a head or a tail is equally likely to fall therefore $p = \frac{1}{2}$ and $q = \frac{1}{2}$. The probability of drawing an ace from a pack of 52 cards is $\frac{1}{13}$.

Events may be independent, dependent and mutually exclusive. An event E is said to be independent of another event F when the actual happening of F does not influence in any degree the probability of the happening of E . If the probability of the happening of E is dependent on, or influenced by the previous happening of F then E is said to be dependent on F . (1)

Two events E and F are said to be mutually exclusive when through the occurrence of one of them, say F , the other event E cannot take place or *Vice Versa*. (2)

Theorem of Addition of Probabilities — When an event may happen in any one of the n different and mutually exclusive ways, E_1, E_2, \dots, E_n with probabilities p_1, p_2, \dots, p_n , then the probability for the happening of the event E is equal to the sum of the probabilities $p_1 + p_2 + \dots + p_n$. (3)

Theorem of multiplication of probabilities * — The probability, p , for the simultaneous or consecutive appearance of several mutually exclusive events is equal to the product $\times p_2 \times p_3 \times \dots \times p_n$. The theorem is called, 'Theorem on compound probability'. A card is drawn from a packet and replaced by a joker, then a second card is drawn. The probability that both cards are aces is $p = p_1 \times p_2 = \frac{1}{13} \times \frac{1}{13}$. If no replacement is made, (Dependent Events), and a second card is drawn, then $p = \frac{1}{13} \times \frac{3}{51}$.

If two coins are tossed, there are altogether 4 ways of their falling

H H H T, T H T T

$$p = \frac{1}{2} \quad \frac{1}{2} \quad \frac{1}{2}, \quad \text{Sum} = 1$$

If n coins be tossed the frequency distribution of the respective chances of n , $n-1$, $n-2$, ..., 3, 2, 1, 0 heads is given by $(\frac{1}{2} + \frac{1}{2})^n$

In general if p and q represent the probabilities of success and failure for a single event ($p+q=1$) the frequency distribution of the Chances of n , $n-1$, $n-2$, ..., 2, 1, 0, successes in the compound event is given by the successive terms of the binomial expansion

$$(p+q)^n = p^n + n p^{n-1} q + \frac{n(n-1)}{2} p^{n-2} q^2 + \dots + q^n$$

$$\text{Or } p^n + nC_1 p^{n-1} q + nC_2 p^{n-2} q^2 + \dots + nC_r p^{n-r} q^r + \dots + q^n$$

The Arithmetic Mean for this is p and $\sigma = \sqrt{n p q}$
(For proof see Appendix)

If n the number of events be large and neither p or

*For proof of these theorems see Appendix

q very small, then $(p+q)^n$ approximates to the regular curve, i.e. the Normal Curve or the Normal Frequency Curve or the Probability Curve or Normal Curve of Error

NORMAL CURVE

Normal Curve—In the Normal Curve as shown in the figure the origin is taken at the centre O, the variable is measured along the x axis and its frequency along the y axis. The chances of a deviation from the centre according to the Normal Curve are given as,

<i>Deviation lying between</i>	<i>Chance</i>
5σ and -5σ	383
6745σ and -6745σ	5
σ and $-\sigma$	682
2σ and -2σ	954

The quantity 6745σ is said to be the Probable error

Thus for a variable there is a chance of 682 in 1000 that a deviation from the Mean will not exceed the standard deviation σ and a chance of 318 in 1000 or nearly 1 in 3 times that it will

Similarly a deviation greater than 2σ will occur 46 in 1000 or nearly 1 in 19 or 20. Following this a probability of 19 to 1 against an occurrence is generally taken, as the criterion of significance though some people use 99 to 1 depending on the nature of the Variables. Tables given above give the probability of obtaining the deviations of any size. Such a table is known as a Table of Probability Integral and may be found in Pearson's Tables for Statisticians and Biometricians.

The equation of the Normal Curve can be written as

$$y = \frac{N}{\sqrt{2\pi}} e^{-\frac{x^2}{2\sigma^2}} \quad \text{or} = \frac{N}{2.506\sigma} e^{-\frac{x^2}{2\sigma^2}}$$

N being the total number of frequencies.

To fit the Normal curve, assign appropriate values (multiples of σ) to x . We can obtain from this eq. the corresponding value for y , or the Ordinates for the curve. After securing some ordinates, the curve can be fitted to the given data. Putting $x=0$, we get the maximum ordinate, to be erected at the Arithmetic Mean.

If the magnitude of the class intervals (i) is constant, then the equation can be written with Ni instead of x . In practice straightforward normal distributions of physical objects are rare except in certain branches of biological science.

A'Priori and Empirical Probabilities.—The probability described above is of the a'priori type i.e. chances are derived from consideration of the possible combinations of factors involved. In the majority of cases in practical life, the factors at work are not definitely known. So Empirical probability is used which is based upon actual observation or experiment. Let m trials be made of which s represent successes and f , failures. The best estimate of the chance of event happening is

$$p = \frac{s}{m}, \text{ and of non-occurrence is } \frac{f}{m}. \text{ Empirical}$$

probability depends on the number of trials, if the number is large, the estimate will also be very accurate. According to life table, out of every 100,000 persons living at age 10, 82,820 survive to age 40, of whom 820 die during the year, 81,455 survive till 41, therefore the probability of a life aged 40, dying within the year will

$$\text{be } \frac{820}{82875} = 01 \text{ and the chance of his surviving the year} = \frac{81455}{82275} = .99.$$

Sampling—For a comprehensive and bulky data, much time, energy and money would be needed for its statistical analysis. From the big mass of data a part or parts may be taken to represent the whole. This small mass selected from the big mass is said to be 'Representative Data' or a sample. The process of such selection is sampling. The whole data is called the population or universe from which samples are taken.

Sampling may be (1) deliberate or purposive with definite objects in view (2) Random with no definite purpose (3) Stratified i.e. to segregate a heterogeneous universe into homogeneous sub groups and to draw from each sub group a sample at random. If (1) and (2) combine, it will be mixed sampling. Random selection consists in picking up at random from a big mass, such a few examples, as can sufficiently represent the whole population. The examples thus selected are studied intensively. As the deliberate selection is likely to be prejudiced so random selection is preferred. Surveys formed are known as sample surveys.

General laws of Statistical Induction (1) The law of Statistical Regularity which lays down that a group of objects chosen at random, from a larger group tends to possess the characteristics of the whole universe. The sample should not be too small as it may be biased or it may not be representative.

Every item in the population must stand an equal chance of being included. Lots may be drawn for randomness and Tippett's Random Numbers may also be used (Random numbers are also given in Fisher and Yates Tables). The larger the sample, the more reliable are its indications.

(2) The law of Inertia of Large Numbers It follows from (1) and according to it, large aggregates are relatively more stable than the small ones. If the numbers involved are of great magnitude, the total change will likely be almost insignificant. For instance, while the production of wheat may differ from place to place, owing to the scarcity of rain, the visit of floods or some other cause, the total production of the World as a whole remains fairly constant.

Both the laws are based on experience and the insurance principles are based on these. The theory of sampling is based on probability.

Sampling fluctuations or Errors of sampling
No sample can afford a perfect representation of the universe from which it is drawn. In spite of precautions to secure randomness, variations occur, due to the elements of chance present in the selection. Such variations are known as sampling Errors or fluctuations. The reliability of the sample depends upon their probable magnitudes.

Measures of Reliability or Tests of significance
In general the results of sample inquiries will show differences that cannot be assigned to any definite cause. Every sample will have its peculiarities in the form of 1. frequency distribution and in the magnitude of 2. its average, 3. standard deviation and 4. skewness.

These differences are the fluctuations and it is the aim of the theory of sampling based on the theory of Probability to supply tests with the help of which it can be determined whether any given fluctuation is statistically significant or not.

We shall deal in this chapter with the significance

Mean, Differences between means, significance of standard deviation and of the correlation co-efficient r

It will be found that a large number of experiments show many different values of the mean, each one departing more or less from the true mean of the entire universe. If the standard deviation of the whole population is σ and we take a large number of random samples of n observations, then the means of the samples will be distributed with a standard deviation $\frac{\sigma}{\sqrt{n}}$. If the universe is normally distributed,

the means also will be normally distributed. If the distribution of the universe is not normal the distribution of the Means of samples still tends to be normal provided the size of the samples is sufficiently large, but in cases of small samples the distribution of the means is not normal.

The standard deviation of the entire population (sometimes called parent population) is not generally known, so we have to take the standard deviation of an observed sample as an estimate of it. The standard deviation of the sampling distribution is then estimated from the standard deviation of a single sample. This estimated value, i.e., the standard deviation of the mean of a random sample, is called the standard error of the mean and is given by

$$\sigma_M = \frac{\sigma}{\sqrt{n}},$$

where σ is the standard deviation of the sample and n the number of observations in it. Probable Error of the Mean $= \frac{.6745 \sigma}{\sqrt{n}}$ (though the probable error is not much used

in practice) = 6745 standard error (nearly $\frac{2}{3}$ S.E.) The best estimate of the mean of the population is $M \pm \sqrt{\frac{\sigma^2}{n}}$. The larger n the smaller the standard error when n is sufficiently large, the standard error is almost negligible. In examining the significance of the Mean of n items x_1, x_2, \dots, x_n for small sample the standard deviation is to be found

by $\sqrt{\frac{\sum(x - \bar{x})^2}{n-1}}$, where $n-1$ represents the number

degrees of freedom for calculation σ . After obtaining \bar{x} and σ , in this way, we obtain the t' statistics which is essentially the ratio of the mean to its standard error or

$$t = \frac{\bar{x} - \mu}{\frac{\sigma}{\sqrt{n}}} = \frac{\bar{x} - \mu}{\frac{\sigma}{\sqrt{n}}}$$

This ' t ' distribution is due to 'Student' ✓

The following table (from Fisher and Yates tables III) gives values of ' t ' corresponding to different values of N the number of the degrees freedom (one less than the total number of observations)

If the calculated value of t' is greater than that given in the table for appropriate value of N , then the mean is significantly different from zero, otherwise not

Table values of ' t ' corresponding to a probability $P = 0.05$ [levels of significance]

<i>N</i>	<i>t</i>	<i>N</i>	<i>t</i>	<i>N</i>	<i>t</i>
1	12.706	13	2.160	25	2.060
2	4.303	14	2.145	26	2.056
3	3.182	15	2.131	27	2.052
4	2.776	16	2.120	28	2.048
5	2.571	17	2.110	29	2.045
6	2.447	18	2.101	30	2.052
7	2.365	19	2.093	40	2.021
8	2.306	20	2.086	60	2.000
9	2.262	21	2.080	$N = \infty \quad t = 1.96$	
10	2.228	22	2.074		
11	2.201	23	2.069		
12	2.179	24	2.064		

When the number of observations is large, calculate $\frac{\sigma}{\sqrt{n}}$ in the usual way

Example—Eleven school boys were given a test in Geometry they were given a month's further tuition and a second test of equal difficulty was held at the end of it. Do the marks give evidence that the students have benefited by the extra coaching?

Boys	Marks 1st Test	Marks 2nd Test	Differences <i>x</i>
1	23	24	+1
2	20	19	-1
3	19	22	+3
4	21	18	-3
5	18	20	2
6	20	22	2
7	18	20	2
8	17	20	3
9	23	23	0
10	16	20	4
11	19	17	-2
			$\frac{+11}{11}$

The problem is 'Is the mean of the differences between the marks of the two tests significantly different from zero?

A Mean = $\frac{11}{11} = 1$ and standard deviation $(\sigma = 2.06)$

$$\sigma = \sqrt{\frac{59}{11-1}} = \sqrt{5}$$

Hence standard error of the mean

$$\sigma_M = \frac{\sigma}{\sqrt{n}}$$

$$\sigma_M = \sqrt{5} \times \frac{1}{\sqrt{11}} \text{ applying 't' test}$$

$$t = 1 \times \frac{\sqrt{11}}{\sqrt{5}} = 1.3$$

178) The calculated value is less than the value of t for $N = 11 - 1 = 10$ in the table. Hence the mean of x is significantly different from zero and the marks are not enough to prove the advantage of extra coaching.

Significance of the difference between two means
 statistical language the problem may be expressed as: Is difference between the means such that they might have been drawn from the same universe by random or are they drawn from two different universes or populations? For a large number of observations in the samples the standard error of the difference

between two means is given by $\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}$ where σ_1 and σ_2

standard deviations of the two independent (as given by two different authorities) and uncorrelated samples n_1 and n_2 are the number of observations in sample.

If the difference between the two means is greater than twice its standard error, then the means are significantly different.

Given the following

	Marks
Mean	$\bar{x}_1 = 130$ $\bar{x}_2 = 127$
S D	$\sigma_1 = 14$, $\sigma_2 = 12$
of boys in Class I & II	$n_1 = 84$, $n_2 = 60$

The problem is to find whether the mean test score of Class I is significantly greater than that of the Class II
 Difference between the Means $= 130 - 127 = 3$

$$\text{of difference} = \sqrt{\frac{196}{84} + \frac{144}{60}} = 2.2 \text{ nearly}$$

The difference between the Mean is less than twice standard error hence the mean test score Class I is not significantly greater than of the Class II. For all samples t test has to be applied — If x_1, x_2 are two sets of observations with means \bar{x}_1 and \bar{x}_2 respectively find expression

$$\frac{\sum (x_1 - \bar{x}_1)^2 + \sum (x_2 - \bar{x}_2)^2}{(n_1 - 1) + (n_2 - 1)} = S^2 \text{ (say)}$$

Where n_1 & n_2 are the number of observations or frequencies. The value of t is given by

$$t = \frac{\bar{x}_1 - \bar{x}_2}{S \times \sqrt{\frac{1}{n_1} + \frac{1}{n_2}}}$$

For the t table the degrees of freedom will be

$$N = n_1 - 1 + n_2 - 1$$

The significance is tested in the same way as for mean

Standard Errors for, Median, for standard deviation, and Mean deviation, etc., are the following —

$$\sigma_{\text{Median}} = 1.253 \sqrt{\frac{\sigma}{n}}, \quad \sigma_{\text{S deviation}} \text{ or } \sigma_{\sigma} = \sqrt{\frac{\sigma}{2n}}$$

$$\sigma_{\text{M Dev}} = 6038 \sqrt{\frac{\sigma}{n}} \quad \text{Probable error} = .6745 \text{ S.E.}$$

$$\sigma_{\gamma_1} = \sqrt{\frac{6}{n}}, \quad \sigma_{\gamma_2} = \sqrt{\frac{24}{n}}, \quad \text{If } \gamma_1 \text{ and } \gamma_2 \text{ are both}$$

than twice (at least) their S.E. then the distribution is not significantly different from the normal form. In when n is large, the error becomes smaller and smaller.

Significance of the Co-efficient of Correlation r

Standard error of $r = \sqrt{\frac{1-r^2}{n}}$. This is approx

true when n is large. In such cases the correlation is taken as differing significantly from zero, if r is more than twice (at least preferably thrice) its standard error. The standard error is generally applied when $n \geq 50$ more. In small samples, however, the significance of r can be determined with the help of 't' tests, which is

by $t = \frac{\sqrt{n-2} \cdot r}{\sqrt{1-r^2}}$ if the value of t is larger than the

given in the table for 't' for $n-1$ degrees of freedom, then r is significantly larger than zero. Moreover Fisher and Yates (Table VI) have given tables for the values of r for P etc., and $N = n-2$. The calculated value of r may simply be compared with the values of r in the table for significance and degree of association.

The 'z' test. I. 'z' test with error of 5%.

correlation between two variables is different in two independent samples, Fisher's 'z' test method is used. According to this method r is transformed into 'z' such that

$$z = \frac{1}{2} \log_e \left\{ \frac{1+r}{1-r} \right\}$$

The values of z corresponding to the values of r are given in Fisher and Yates tables

The standard error of z is $\frac{1}{\sqrt{n-3}}$ and the standard error of difference between two z 's is

$$\sqrt{\frac{1}{n_1-3} + \frac{1}{n_2-3}}$$

n_1 and n_2 are the numbers of pairs in the two series. If the difference between the two z 's is greater than twice its standard error, then the difference is significant.

Analysis of Variance

The analysis of variance is a useful method in scientific studies especially in Agriculture and Biology. It may briefly be explained as follows. It is known that the variance of a variable is obtained from the sum of the squares of the deviations of items from the general Mean. The sum of squares can be split up into two portions. Suppose we have yields per acre of 6 plots of wheat, three of which are of variety a and three of variety b .

a	30	32	22
b	20	18	16

The total sum of squares is separated into one

due to variation *between* the varieties. Let the mean all observations x_1, x_2, \dots be denoted by \bar{x} , which in case is $\frac{138}{6} = 23$. The mean of a , \bar{x}_a is $\frac{84}{3} = 28$ and of b is $\frac{54}{3} = 18$.

(2) Find $\sum_1^6 (x - \bar{x})^2$ which in this case is $(30 - 23)^2 + (32 - 23)^2 + (22 - 23)^2 + (20 - 23)^2 + (18 - 23)^2 + (16 - 23)^2 = 49 + 81 + 1 + 9 + 25 + 49 = 214$.

(3) Find the sum of squares for within the variety for (a), it is $(30 - 28)^2 + (32 - 28)^2 + (22 - 28)^2 = 4 + 16 + 36 = 56$ for (b) it is $(20 - 18)^2 + (18 - 18)^2 + (16 - 18)^2 = 4 + 0 + 4 = 8$.

The total sum is $56 + 8 = 64$ i.e. we have for $\sum_1^3 (x - \bar{x}_a)^2$ and $\sum_4^6 (x - \bar{x}_b)^2$.

(4) Find the sum of squares for *between* the varieties. This is given by $3 \times [(28 - 23)^2 + (18 - 23)^2] = 3 [25 + 25] = 150$. (We obtain deviations of the means of a and b from the general mean square and then sum. The sum is multiplied by 3 because each value represents mean of 3 plots) i.e. we have found $3(\sum(\bar{x}_a - \bar{x})^2 + \sum(\bar{x}_b - \bar{x})^2)$ or $3 \sum(\bar{x}_i - \bar{x})^2$ where \bar{x}_i represents the mean of group i .

(5) Adding (3) and (4) we obtain the sum as $64 + 150 = 214$, which is the same as in (2).

The sum of squares can always be divided in this way into two components or parts.

In general if there are k groups and n simple observations in each group, then

$$\sum_{i=1}^k (x - \bar{x})^2 = \sum_{i=1}^k \sum_{j=1}^n (x - \bar{x}_i)^2 + n \sum_{i=1}^k (\bar{x}_i - \bar{x})^2 \quad \text{In the above } n=3$$

and $k=2$.

The degrees of freedom corresponding to the sum of squares are given for,

Total	Within	Between
$(nk - 1)$	$k(n - 1)$	$k - 1$

and the variance is obtained by dividing the sum of squares by the degrees of freedom. The analysis of variance is set up in the following table —

Source of Variation	Sum of Squares	Degrees of Freedom	Variance
Within the Varieties	64	4	16
Between the Varieties	150	1	150
	<hr/> 214	<hr/> 5	<hr/>

The variance for between the varieties is very high as compared to that for within varieties. Generally if the variances are significantly different, there is some specific cause of variation. To test the significance find the ratio $v_2 = F$ where v_1 denotes the variance for 'within the varieties' (known also as Error Variance) v_2 denotes the variance for 'between the varieties.'

Tables have been constructed by Snedecor for F , for n_1 and n_2 degrees of freedom, n_1 being the degrees of freedom for 'within' and n_2 for 'between' the varieties.

If the calculated value of F is greater than the value of F in the tables for n_1 and n_2 degrees of freedom, then the differences between the varieties is significant

Logarithms also can be used. Fisher has given tables for z for the testing the significance where

$$z = \frac{1}{2} \log_e F$$

Exercise X.

- 1 Find the probability of throwing 9 with three dice

$$\text{Ans. } \frac{25}{216}$$

- 2 In the Binomial distribution $(p+q)^n$ find the Mean and standard deviation if $p=3$ and $n=20$. What is q ?

$$\text{Ans } 6.204, 7$$

- 3 A bag contains 5 white and 7 black balls. If 2 balls are drawn, what is the probability that one is white and the other black?

$$(M A 1943) \text{ Ans } \frac{{}^5C_1 \times {}^7C_1}{{}^{12}C_2} = \frac{35}{66}$$

- 4 In solved Ex 1, let x be 4, 1, 0, 3, 4, -4, 2, -2, 1, 1, 1. Determine the significance

$$\text{Ans. No}$$

- 5 One purse contains 1 sovereign and 3 shillings, a second one contains 2 sovereigns and 4 shillings, and a third one contains 3 sovereigns and 1 shilling. If a coin is taken out of the purses selected at random, find the chance that it is a sovereign

6.	Number of persons examined	Mean height	σ
(1)	600	67.5"	2.55
(2)	1300	68.6"	2.5

Find whether the persons in (2) are significantly taller than those from (1)

Ans. Yes.

7 Apply 't' test to find whether correlation is significant, if $r = .6$ and $n = 33$

Ans. Yes

8 Apply 'z' test to determine the significance between two correlations given by

$$r_1 = .472, r_2 = .377, n_1 = 42, n_2 = 39$$

Ans. No

9 Fit a Normal curve for a frequency distribution whose class interval is 10, σ is 21, Mean = 80.6, $n = 300$

Hint — Take x as $\pm \frac{1}{2} \sigma$ or $\pm \frac{3}{2} \sigma$ to find ordinates
Trace the curve

10 Set up a table of analysis of variance, for

Plots	Varieties			
	(1)	(2)	(3)	(4)
a	140	145	150	160
b	100	110	120	125
c	200	180	160	150

11. Give two series

x_1	21.3,	20.8,	23.7,	24.3,
x_2	20.2,	16.9,	18.2,	16.7

~~Test whether the difference between the two means~~

12 Calculate the sampling error of the mean in Q 24

Ex I

(C St 1945)

Ans 0172.

13 Set up a table of analyses of variance and find F, for the varieties of gram in the following plots

1	27.6	32.4	23.4
2	19.2	18.6	16.5

Ans 12.8

14 Set up a table of analysis of variance for yields of four strains of wheat planted in five randomised blocks

Strains		Blocks		
a	30	35	38	36
b	29	40	42	44
c	34	45	50	36
d	30	50	45	38

15 A bag contains 6 white and 9 black balls. Two drawings of 4 balls are made such that, (a) the balls are replaced before the second trial (b) the balls are not replaced before the second trial. Find the probability that the first drawing will give 4 white and the second 4 black balls in each case

Ans $\frac{6}{65}, \frac{21}{55}$

(Indian Audit and Accnts 1945)

16 A can hit a target 3 times in 5 shots, B 2 times in 5 shots, C 3 times in 4 shots. They fire a volley. What is the probability that 2 shots hit?

17. A bag contains K similar balls. A part of or all balls are drawn.

What is the probability of drawing (1) an even number (2) odd number of balls. (M A Aligarh 1943)

$$\text{Ans } \frac{k-1}{2-1} \quad \frac{k-1}{2-1}$$

18. A and B throw with one dice for a prize of Rs 11 which is to be one by the player who first throws 6. If A has the first throw what are their respective expectations?

(Hyderabad B Sc 1945) Ans Rs 6 & 5

19. It is 8 : 5 against a person who is now 40 years old living till he is 70 and 4 : 3 against person now 50 living till he is 80. Find the probability that one at least of these persons will be alive 30 years hence.

$$\text{Ans } \frac{59}{91} \quad (\text{Hyderabad B A 1945})$$

CHAPTER XII

INTERPOLATION AND GRADUATION

In Chapter IV Interpolation was explained graphically. In this chapter we shall deal with formulæ for interpolation.

(1) Newton's formula for equidistant spaces (equal gaps or equal intervals)

Let x be the independent variable or the argument, y or $f(x)$ the corresponding value for x or the function of x .

Given	x	y or $f(x)$
	a	$f(a)$
	$a+w$	$f(a+w)$
	$a+2w$	$f(a+2w)$
	$a+3w$	$f(a+3w)$

—

—

To find the value of y or $f(x)$ for a value of x lying, somewhere between a and the last item in x say for $a+xw$ Newton's formula gives

$$\begin{aligned}
 f(a+xw) &= f(a) + x \Delta f(a) \\
 &+ \frac{x(x-1)}{2} \Delta^2 f(a) + \frac{x(x-1)(x-2)}{3! = 3 \times 2} \Delta^3 f(a) \\
 &+ \frac{x(x-1)(x-2)(x-3)}{4! = 4 \times 3 \times 2 = 24} \Delta^4 f(a) \\
 &+ \frac{x(x-1)(x-2)(x-3)(x-4)}{5! = 120} \Delta^5 f(a) + \dots
 \end{aligned}$$

Where $\Delta f(a) = f(a+w) - f(a)$, known as the first difference of $f(a)$ or Difference of first order.

$\Delta^2 f(x) = \Delta f(x+w) - \Delta f(x)$ known as the difference of $f(x)$ or difference of second order

$\Delta^3 f(x) = \Delta^2 f(x+w) - \Delta^2 f(x)$ known as difference of third order

$$\Delta f(x+w) = f(x+2w) - f(x+w), \quad \Delta^2 f(x+w) = \Delta f(x+2w) - \Delta f(x+w) \text{ and so on.}$$

Example 1 — The population of India in the following four censuses, is given in millions, to find the population for 1926

x	$f(x)$	Δ	Δ^2	Δ^3
1901, x	294			
		21		
1911, $x+w$	315		-17	
		4		47
1921, $x+2w$	319		30	
		34		
1931, $x+3w$	353			

(M.A. Aligarh 1943)

To find the population for 1926, put $x+w=1926$, since x is 1901 and w is 10, $\therefore x=2$

The first difference $\Delta f(x)$ is given by subtracting the upper value from the lower value or entry in $f(x)$. Second differences Δ^2 are obtained by subtracting the upper value in column Δ from the lower value and so on.

These differences are placed in between in column Δ , Δ^2 , Δ^3 as shown in the table

In this way we proceed further. When this table known as Difference Table has been formed, we apply

Newton's formula, taking the topmost values for $\Delta f(a)$, $\Delta^2 f(a)$ etc. (known as the leading diagonal)

$$\therefore f(1926) = 294 + \frac{1}{2} \times 21 + \frac{\frac{5}{2}(\frac{5}{2}-1)}{2} \times (-17) +$$

$$\frac{\frac{5}{2}(\frac{5}{2}-1)(\frac{5}{2}-2)}{6} \times 47 = 294 + \frac{1695}{48} = 329 \frac{5}{16} \text{ millions.}$$

Newton's formula is also written in the form

$$u_x = u_0 + x \Delta u_0 + \frac{x(x-1)}{2} \Delta^2 u_0 + \frac{x(x-1)(x-2)}{6} \Delta^3 u_0 + \dots$$

u_0 stands for $f(a)$ and u_x for the interpolated value.

The series will terminate after some differences. The results obtained will in general be approximate depending largely on the nature of data and circumstances governing the data being normal

2. Lagrange's formula for unequal intervals Given the following

x	$f(x)$
a	$f(a)$
b	$f(b)$
c	$f(c)$
d	$f(d)$
e	$f(e)$
\dots	\dots
\dots	\dots
\dots	\dots

where a, b, c, d, \dots differ by unequal gaps or intervals. To find the value for any other x , the Lagrange's formula is used, which is stated as

$$f(x) = f(a) \times \frac{(x-b)(x-c)(x-d)(x-e)}{(a-b)(a-c)(a-d)(a-e)} +$$

$$\begin{aligned}
 & f(b) \times \frac{(x-a)(x-c)(x-d)}{(b-a)(b-c)(b-d)} \\
 & + f(c) \times \frac{(x-a)(x-b)(x-d)}{(c-a)(c-b)(c-d)} + \\
 & f(d) \times \frac{(x-a)(x-b)(x-c)(x-e)}{(d-a)(d-b)(d-c)(d-e)} + \dots
 \end{aligned}$$

Example 2 — Given

x	$f(x)$
14	68.7
17	64
31	44
35	59.1

(M. A. Punjab 1942)

To find the value for $x=27$

In Lagrange's formula put $x=27$, $a=14$, $b=17$, $c=31$ and $d=35$

$$\begin{aligned}
 f(27) &= 68.7 \times \frac{(27-17)(27-31)(27-35)}{(14-17)(14-31)(14-35)} \\
 &+ 64 \times \frac{(27-14)(27-31)(27-35)}{(17-14)(17-31)(17-35)} \\
 &+ 44 \times \frac{(27-14)(27-17)(27-35)}{(31-14)(31-17)(31-35)} \\
 &+ 59.1 \times \frac{(27-14)(27-17)(27-31)}{(35-14)(35-17)(35-31)} \\
 &= 49.3 \text{ nearly}
 \end{aligned}$$

Lagrange's formula is also written as —

$$\begin{aligned}
 u_x &= u_0 \times \frac{(x-b)(x-c)}{(a-b)(a-c)} \\
 &+ u_1 \times \frac{(x-a)(x-c)}{(b-a)(b-c)} + \dots
 \end{aligned}$$

Central Difference Formulae—The following we known formulae are also used for interpolation, the argument $x=a$, being taken in the middle and the difference table being in the form

argument x	$f(x)$ or entry
$a-2w$	$f(a-2w)$
$a-w$	$f(a-w)$
a	$f(a)$
$a+w$	$f(a+w)$
$a+2w$	$f(a+2w)$
\vdots	\vdots

(1) Gauss formula

$$\begin{aligned}
 f(a+xw) = & f(a) + x \Delta f(a) + \frac{x(x-1)}{2} \Delta^2 f(a-w) \\
 & + \frac{(x+1)x(x-1)}{3!} \Delta^3 f(a-w) \\
 & + \frac{(x+1)x(x-1)(x+2)}{4!} \Delta^4 f(a-2w) + \dots
 \end{aligned}$$

(2) Stirling formula

$$\begin{aligned}
 f(a+xw) = & f(a) + x \frac{\Delta f(a) + \Delta f(a-w)}{2} \\
 & + \frac{x^2}{2!} \Delta^2 f(a-w) + \frac{x(x^2-1^2)}{3!} \times \\
 & \frac{\Delta^3 f(a-w) + \Delta^3 f(a-2w)}{2} \\
 & + \frac{x^2}{4!} (x^2-1^2) \Delta^4 f(a-2w) + \dots
 \end{aligned}$$

(3) Bessel's formula

$$\begin{aligned}
 f(a+xw) = & \frac{1}{2} \{f(a) + f(a+w)\} + (x-\frac{1}{2}) \Delta f(a) \\
 & + \frac{x(x-1)}{2!} \frac{1}{2} \{ \Delta^2 f(a-w) + \Delta^2 f(a) \} + \dots
 \end{aligned}$$

The above formulae can be written in the form of u_n

after changing $f(a+xw)$ to $u_x f(a)$ to u_0 , $f(a-w)$ to u_{-1} and so on. Proofs of these formulae are given later on.

The central difference formulae are applicable to important problems such as Subtabulation, Estimation of population for individual ages when populations are given in age groups, inverse interpolation, and derivatives of a function. The detailed account will be found in Calculus of observation by Whittaker and Robinson, Chap. IV.

Graduation

Let u_1, u_2, \dots, u_n be the set of values as a result of observation or experience, corresponding to equidistant values of the argument. If these values have been derived from observations of some natural phenomenon, they will be affected by errors of observation, if they are statistical data they will be affected by irregularities arising from the accidental peculiarities of the data. If we form a table of the differences $\Delta u_1 = u_2 - u_1$, $\Delta u_2 = u_3 - u_2$, etc., it will generally be found that these differences are not regular, so that the difference table cannot be used for the purposes to which a difference table is usually put, namely for interpolated values of u , or differential coefficient of u , with respect to its argument.

Before the difference table is used, we must perform a process of 'smoothing' that is we must find another sequence

$u'_1, u'_2, u'_3, \dots, u'_n$ whose terms differ as little

as possible from the term of the sequence u_1, u_2, \dots, u_n

but having regular differences. This smoothing leading to the formation of u'_1, u'_2 is called the graduation or adjustment of the observations for smoothing of the data. For example, mortality is a function of age and if the mortality rates are tabulated at successive ages on the basis of observed numbers living and dying during year or period of years, the resulting series will show a definite trend, having however, the fluctuations of sampling. The series must be smoothed before it is used for actuarial purposes and it is the object of graduation to remove such disturbances in a systematic manner, without spoiling the observed facts as far as possible. Smoothing can be done by using a freehand curve fitting the data and by using the method of moving averages. There are several methods of graduation such as of Woolhouse and of Spencers. These are rather difficult to be given here. They are dealt with in Calculus of observation by Whittaker and Robinson. (See also Yule and Kendall)

Exercise XI.

1. Given the cubes as follows, find the cubes of 32.3 and 33.1.

Number,	31,	32,	33,	34,	35.
Cubes	29791,	32768,	35937,	39304,	42875.

Ans. 33698.267 and 36264.691.

2. Given
- | | | | | |
|-----|---------|---------|---------|---------|
| x | 2.5, | 3, | 3.5, | 4, |
| y | 24.145, | 22.043, | 20.225, | 18.644, |
| | 4.5, | 5. | | |
| | 17.262, | 16.047. | | |

Find for $x=2.75$,

$A = 24.05$

3	Marks obtained	Candidates
	Not more than 45	447
	50	484
	55	505
	60	511
	65	514

Estimate the number of candidates securing not more than 48 Marks

Ans 471

4 The following are the annual premiums required by an Insurance Company to secure Rs 1,000 with profits by making twenty payments in all. What would be the premium payable at the age of 26 next birthday?

Age next birthday	Years	20	25,	30,	35
	Rs	36,	39,	42 12	47 6

Ans Rs 39 12 ans (nearly)

5	x	$f(x)$	x	$f(x)$
	25	52	40	84 1
	30	67 3	50	92 4

Find the approximate value for $x=35$

Ans 77 5

6 The pressure of wind in pounds per square foot, corresponding to the Velocity in miles per hour has been determined by experiment to be approximately as follows —

Velocity	10,	20	30	40
Pressure	1 1,	2,	4 4,	7 9

Estimate the pressure for a velocity of 25 miles per hour

Ans 3 03

7 Death Rates per 100,000 population

	<i>Typhoid</i>	<i>T B</i>
1906	31.3	157.1
1909	21.1	139.3
1912	16.5	129.8
1915	12.4	127.7

Estimate the Death Rates for 1910

Ans. 19.19 and 135.25.

8	x	5,	7,	11,	13,	17.
	$f(x)$	150,	392,	1452,	2366,	5202.

Find the function by Lagrange's formula when the argument has the values 9 and 6.5 respectively

Ans. 810 and 316.875.

9	<i>Ages.</i>	<i>Proportion occupied per 10,000 of total</i>
	10—15 years,	193.5
	15—20	880
	20—25	933
	25—35	1636
	35—45	1201
	45—55	830

Determine the number under 30 years

Hint—Take cumulatives at 15, 20, 25 etc and apply Lagrange's formula, with $x=30$. In a frequency distribution it is better to take cumulatives

Ans. 2879

10 In the following table h is the height above sea level and p the barometric pressure. Calculate p when $h=5280$.

$h=0$,	2753,	4763,	6942,	10593.
$p=30$,	27,	25,	23,	20

(SI A. Afgarh 1942) *Ans. 24.5.*

11 In Q 2 find the value for $x=4\frac{1}{2}$ by Gauss and Stirling formula

Ans 183 nearly

12 Given $\sin 45^\circ = 7071$ $\sin 50^\circ = 766$

$\sin 55^\circ = 8192$, $\sin 60^\circ = 866$ find $\sin 52^\circ$

(M A 1942) *Ans 788*

13 Estimates the population in 1925 of a place having the following record —

Year	Population in thousands	Year	Population in thousands
1891	46	1921	93
1901	66	1931	101
1911	81

Find for 1928

(B Com Supp 1945) *Ans 305.513*

17. Given

Year	1835,	1840,	1845,	1850,	1855.
Cost in Rs. 1,000 (y)	5526,	4577,	5	5395,	5890,
	y_0	y_1	y_2	y_3	y_4

The problem is to find the value for 1845. This can be done by the method of differences with the help of the following difference table

	Δ	Δ^2	Δ^3	Δ^4	Δ^5
y					
y_0	$y_1 - y_0$				
y_1	$y_2 - y_1$	$y_2 - 2y_1 + y_0$			
y_2	$y_3 - y_2$	$y_3 - 2y_2 + y_1$	$y_3 - 3y_2 + 3y_1 - y_0$		
y_3	$y_4 - y_3$	$y_4 - 2y_3 + y_2$	$y_4 - 3y_3 + 3y_2 - y_1$	$y_4 - 4y_3 + 6y_2 - 4y_1 + y_0$	
y_4	$y_5 - y_4$	$y_5 - 2y_4 + y_3$	$y_5 - 3y_4 + 3y_3 - y_2$	$y_5 - 4y_4 + 6y_3 - 4y_2 + y_1$	$y_5 - 5y_4 + 10y_3 - 10y_2 + 5y_1 - y_0$
y_5					

There are four known quantities, so put the fourth difference Δ^4 equal to zero to have a relation between y 's,

$$y_4 - 4y_3 + 6y_2 - 4y_1 + y_0 = 0 \text{ putting the values of } y_0, y_1,$$

$$\text{We get } 6y_2 = 4(4577 + 5395) - (5526 + 5890)$$

Which gives $y_2 = 4745$ In practice for such questions take up to fifth differences the data to get approximate results

18	Given	10,	20,	30,	40,	50,
		48.8,	42,	34.4,	27.6,	?
		60,	70,	80,	90	
		14.3,	9.2,	5.5,	3.3,	

Hint.—Put $\Delta_4 = 0$, then taking $y_7 - 4y_6 + 6y_5 - 4y_4 + y_3 = 0$, result is $y_5 = 20.65$

19.	Years	1916,	1918,	1920,
	Manufacture of Cement	39,	84,	?
	In India in 1000 tons.			
		1922,	1924,	1926.
		151,	264,	388
		(M. A 1942). Ans. 95.9.		

20 Use Bessel's formula to find $f(35)$ given $f(x)$ 20, 30, 40 and 50 to be 51203, 43931, 34563 and 318.

(I. C. S. 1936). Ans. 39431.

21. A student's union had the following numbers of members its roll since 1935, 1935. —36, 37, 37, 39, 40, 1941, 42, 1944, 95, 817,—, 798, 770, 722, ? 707, 711, 746

Use the method of interpolation to make the best estimates you can of the numbers in 1937 and 1941.

(C St 1945). Ans. 8.158, 705.8.

22 Obtain by a graphical method the missing figure in the following table of one per cent values of chi square and check the result by an algebraic method

Degrees of Freedom	1,	2,	3,	4,	5,	6,	7
1% chi sq	6.64,	9.21,	11.34,	13.28	×	16.81,	18.48
Degrees	8 20.07	9 21.67					

(Indian Audit and Accounts 1944).

23 Given the population of a country in millions as —

1901	1911	1921	1931	1941
282	318	339	352	388

Estimate the population for 1936 by an algebraic and also by means of graph and account for the difference if any

Ans 36.425 (Indian Audit and Accounts 1945)

24 Given sales in Rs (000) as 1937, 38, 39, 40, 41, 42, 1943, 800, 850 —, 790, 720, —, 810.

Determine the best estimates for 1939 and 1942

(U Com Punjab 1946) Ans 840, 685

CHAPTER XIII

ASSOCIATION OF ATTRIBUTES, CONTINGENCY
 χ^2 TEST AND GOODNESS OF FIT

The method of correlation described before is to find out the relationship between two series having class intervals and frequencies. In this chapter we shall briefly deal with association between two attributes having class frequencies.

Definitions—Let A, B, C, ... denote the presence of several attributes, and a, b, c, \dots the absence of those attributes. Thus if B represents the attribute 'blindness' will represent 'non-blindness' i.e. 'sight'. If A stands for 'deafness', a stands for 'non A' i.e. 'hearing' and so on. We class all the members of which possess the attribute A, is called the class A, while all the members of which possess the attribute B the class B and so on. The number of observations assigned to any class is known as the frequency of the class or the class frequency. Combination of attributes are denoted by grouping together the letters that indicate the attributes concerned. AB represents the combination of deafness and blindness, aB , non blindness and deafness. Combination of capital letters B stands for positive attributes and ab , for negative attributes. AB and ab are thus pairs of contraries. 'A' which specifies only one attribute is called a class of the first order, AB specifying two attributes, a class of the second order.

All the classes of the same order which equal to the total number of attributes, form an Aggregate of

frequencies of that order. Thus ab , Ab , ab , aB are an aggregate of frequencies of the second order. When no attributes are specified, the total number of observations is denoted by n and is reckoned as a frequency of order zero. While tabulating, class frequencies should be arranged so that frequencies of the same order and frequency belonging to the same aggregate are kept together. It may be noted that, A will denote the number of A 's i.e. objects possessing attribute A , a will denote the number of a 's i.e. the objects not possessing attribute A on

AB will denote, the number of AB s i.e., the objects possessing attributes A and B and so on for others.

71- In a table for the case of 3 attributes, twenty seven frequencies will occur, 1 of order zero $= n$, 6 of the first order A, B, C, a, b, c , 12 of the second, and 8 of the third order $AB, AC, BC, Ab, Ac, Bc, ab, bc$.

In general for k attributes, there are 3^k distinct class frequencies, if n is counted.

Any class frequency can always be expressed in terms of class frequencies of higher order. Thus $A + a = n$, $B + b = n$, $AB + Ab = A$, $AB + aB = B$, $ab + aB = a = n - A$ and $AB = ABC + ABc$. Every class frequency can thus be expressed in terms of the frequencies of the highest order, of order k . The classes specified by k attributes i.e. those of the highest order, are termed the ultimate class frequencies. Thus

$$A = AB + Ab = ABC + AbC + Abc.$$

Every class frequency can be expressed as a sum of certain of the ultimate class frequencies. If the

ass-frequencies are given, the frequencies of the positives
 asses, including n can be worked from the relations
 given above. The number of ultimate class frequencies
 2^1 and the 3^1 frequency may all be expressed in terms
 2^1 ultimate class frequencies or of the 2^1 positive class-
 frequencies.

Criterion and Tests of Independence of Attributes—
 there is no relationship of any kind between two attri-
 butes A and B, we expect to find the same proportion of
 A amongst the B's as amongst the not-B's. Two such
 related attributes may be termed as independent and the
 criterion of independence for A and B is

$$\frac{AB}{B} = \frac{Ab}{b} \quad (1) \text{ This criterion may be put into}$$

different but more convenient form as

$$\frac{AB}{B} = \frac{AB + Ab}{B + b} = \frac{A}{n} \quad (2)$$

$$\text{From this we have } \frac{AB}{B} = \frac{A}{n}, \quad \frac{AB}{A} = \frac{B}{n}.$$

$$\text{or } AB = \frac{A \times B}{n}$$

$$\text{and } \frac{AB}{n} = \frac{A}{n} \times \frac{B}{n}, \text{ which is frequently applied}$$

$$\text{From (1) also follows that } Ab = \frac{A \times b}{n}$$

The third form of the test of independence is

$$AB \times ab = \frac{A \times B \times a \times b}{n^2} \quad aB \times Ab \text{ being equal to}$$

the same fraction, therefore, from this follows,

$$AB \times ab = aB \times Ab$$

Association of Attributes—Let the attributes A and B be not independent but related in some way or other. Then if $AB > \frac{A \times B}{n}$ A and B are said to be positively associated or simply associated. If $AB < \frac{A \times B}{n}$ A and B are negatively associated or simply disassociated. (Exercise VII 6) It may be noted that in Statistics attributes are to be associated only when they appear in a large number of cases than they are expected to if they are independent.

To measure the degree of association there are several coefficients that have been devised but simplest is

$$Q = \frac{AB \times ab - Ab \times aB}{AB \times ab + Ab \times aB}$$

If $Q=0$ the attributes are independent if $Q=1$ they are completely associated and if -1 they are completely disassociated. The attributes can be put in the form of a Table with either A or B on the column or row having two rows and two columns thus (2×2 fold)

Attribute	Attribute		Total
	B	b	
A	AB	Ab	A
a	aB	ab	a
Total	B	b	n

Contingency Tables and Co-efficient of Contingency.—Let the classification of the attribute A be s -fold and that of B's t -fold. There will be st classes of the type $A_i B_m$ (i and m may take any values 1, 2, . . .). Let the frequencies of A's be denoted by (A_i) and of B's by (B_m) and of $A_i B_m$ by $(A_i B_m)$ and so on. The data can be set out in the form of a table of t rows and s columns. The table described above is fourfold (2×2 classification)

A general contingency table is of the form ($s \times t$ fold)

Attributes		A			Total
B		A_1	A_2	A_s	
	B_1	$(A_1 B_1)$		$(A_s B_1)$	(B_1)
	B_2	$(A_1 B_2)$			
	B_t	$(A_1 B_t)$		$(A_s B_t)$	(B_t)
	Total	(A_1)		(A_s)	n

The frequency of any class $A_i B_m$ is entered in the Compartment or cell common to the i -th column and the m -th row. The frequency falling in a cell is said to be the cell frequency. If A and B are completely independent for all values, the $(A_i B_m) = \frac{(A_i) \times (B_m)}{n} = (A_i B_m)'$.

If A and B are not completely independent $(A_i B_m)$ and $(A_i B_m)'$ will not be identical. Let the $(A_i B_m) - (A_i B_m)'$ be denoted by d_{im} .

The co efficient of association or the co efficient of square contingency is given according to Pearson by,

$$C = \sqrt{\frac{\psi^2}{n + \psi^2}} \text{ where } \psi^2 = \sum \left(\frac{d_{im}^2}{(A_i B_m)'} \right)$$

ψ^2 (chi square) is square contingency and $(A_i B_m)'$
 $= \frac{A_i \times B_m}{n}$

A simpler form due to Yule is $C = \sqrt{\frac{S-n}{S}}$ where

$S = \sum \frac{(A_i B_m)^2}{(A_i B_m)'}$, where $A_i B_m$ are the actual observed frequencies.

It is desirable for the calculation of C, to use a (5×5) fold classification.

General procedure — To find ψ^2 , first of all calculate the frequency which would be expected in each cell on a null hypothesis i.e., on the assumption that the two attributes are not associated with another at all i.e., $(A_i B_m)'$ for all i and m. Subtract this ex-

frequency from the actual observed frequency in each cell square these differences and divide by the frequency $(A_i B_m)'$ to get ψ^2 . If the null hypothesis

correct χ^2 and C will be zero. To test the contingency the Calculated Value of χ^2 may be compared with the Values given by Fisher (Fisher and Yates Tables IV) for N degrees of freedom for Probability $P = 0.05$ (5 percent level of significance). If the Calculated Value is greater, then the Null hypothesis is disproved and thus there is a significant association. The degree of freedom are given by $N = (s-1)(t-1)$ where s is the number of columns and t the number of rows (e.g. See Exercise XII 9).

Table of χ^2 (5 per cent level of significance) $P = 0.05$

N	χ^2	N	χ^2	N	χ^2
1	3.841	11	19.675	21	32.671
2	5.991	12	21.026	22	33.924
3	7.815	13	22.362	23	35.172
4	9.488	14	23.685	24	36.415
5	11.070	15	24.996	25	37.652
6	12.592	16	26.296	26	38.885
7	14.067	17	27.587	27	40.113
8	15.507	18	28.869	28	41.337
9	16.919	19	30.144	29	42.557
10	18.307	20	31.41	30	43.773

Goodness of Fit—The χ^2 distribution leads to tests of the correspondence between theory and fact and is described as a test of the goodness of fit. If an observed frequency distribution of a variable is given and we want to examine the validity of some hypothesis about it, this can be done by calculating the expected or theoretical frequencies and examining the agreement or 'goodness of fit' of the observed and theoretical frequencies with the

help of $\chi^2 = \sum \frac{(f' - f)^2}{f}$ where f' denotes the observed actual frequencies and f , the theoretical frequencies. The whole working is the same as for χ^2 in contingency described above. The value of χ^2 may be compared from the Tables (Fisher and Yates). Further if the probability is very low, it will mean a poor fit, if high then the fit is excellent and so on. (See Exercises No. 13).

Contingency tables with Small Frequencies, Yates corrections

If the number of frequencies in one or more compartments of the table is small (less than 5) certain changes have to be made to obtain better results.

Yates correction is made in the smallest frequency, i.e., add $\frac{1}{2}$ to the smallest frequency in the contingency table and adjust other frequencies so that the marginal totals remain the same.

e.g.,

	Attacked by disease	Not attacked	
Inoculated	10	3	13
Not Inoculated	2	5	7
	12	8	20

In the table the frequencies according to Yates correction are changed to

9.5	3.5	13
2.5	4.5	7
12	8	20

The rest of the procedure is the same as for χ^2 distribution. In the above example $\chi^2 = 2.6955$. Comparing from

he tables for one degree of freedom the result is not significant.

Exercise XII.

1 If A and B are independent attributes, how many AB will there be in 1000 observations if there are 100 A's and 400 B's? What will be the number of ab 's?

$$\text{Sol — Using } AB = \frac{A \times B}{n} = \frac{100 \times 400}{1000} = 40.$$

$$\text{Again } ab = \frac{a \times b}{n} = \frac{900 \times 600}{1000} = 540.$$

2 Given the actual observations as, A (Vaccinated people)=30, B (not attacked by small-pox)=60, $n=150$ AB (people who were Vaccinated and not attacked by small-pox)=12 Are the attributes A (Vaccination) and B (exemption from attack) independent?

Ans. Yes, i.e. Vaccination and exemption are not related at all.

3. In Q. 2, given ab (people not vaccinated and attacked)=58, are a and b independent? No.

4. In Q. 2 if $AB=15$; $ab=68$, $Ab=20$, $aB=51$, are A and B independent? Use the test, $AB \times ab = aB \times Ab$ Yes.

5 If the second order frequencies have the values, $AB=110$, $aB=90$, $Ab=290$, $ab=510$ test the independence of A and B Ans No.

6 The attributes in Q 2 are placed in the form of table as

	A	a	n
B	60	10	70
b	20	10	30
n	80	20	100

Test the association

Sol — Applying the test of association $AB > \frac{A \times B}{n}$

we have 60 is greater than $\frac{80 \times 70}{100}$ hence the vaccination exemption from attack are positively associated

Also $ab = 10$ and is greater than $\frac{a \times b}{n} = \frac{20 \times 30}{100}$,

and so a and b also possess positive association. For Attributes A and b we find $Ab = 20$ is less

$\frac{A \times b}{n} = \frac{80 \times 30}{100}$ they are negatively

Similarly a and B are disassociated

7 Test association between injection against typhoid and exemption from attack from the contingency table

	Not attacked	Attacked	
Injected	270	10	280
Not Inj	480	60	540
	750	70	820

Ans Associated positive

8 Determine the Co efficient of association for Q 6

Ans

9 Find χ^2 and test for association the following data

	A_1	A_2	A_3	
B_1	215	325	60	600
B_2	135	175	90	400
	350	500	150	1000

Sol—First construct the table for expected frequencies, of Independence Values by finding

$$(A_i, B_m)' = \frac{A_i \times B_m}{n}, \text{ table is}$$

A_1	A_2	A_3	
210	300	90	600
140	200	60	400

thus $140 = \frac{350 \times 400}{1000}$ and $300 = \frac{500 \times 600}{1000}$

$$\chi^2 = \frac{(215-210)^2}{210} + \frac{25^2}{300} + \frac{(90-60)^2}{60} = 30.5$$

early Degrees of freedom are $(3-1)(2-1)=2$ and for χ^2 from the table $\chi^2=5.9$ The calculated value is much greater than this value hence the Null hypothesis departs significantly from independence and there is significant association and $C = \sqrt{\frac{(30.5)}{1000+(30.5)}}$

10 Is there a significant association between A and B from the following (2×2) table?

	A_1	A_2	
B_1	$a, 64$	$b, 26$	90
B_2	$c, 21$	$d, 49$	70
	85	75	160

Sol — For (2×2) table ψ^2 can also be determined from the formula

$$\psi^2 = \frac{(a+b+c+d)(ad-bc)^2}{(a+b)(a+c)(b+d)(c+d)} \quad \text{Ans Yes}$$

11 Determine the coefficients Q and C for the table and compare these with Yule's coefficient C

Attributes	1	2
1	450	242
2	36	272

Ans. Q = 86 and C =

12 Given the following contingency table for Hair Colour (5 categories) and Eye Colour (5 categories). Find the value of C. Is there good association?

0	0	2	10	11
1	13	69	189	13
5	96	336	91	6
22	89	32	5	0
3	6	1	0	0

Ans 73, yes

13. Examine the goodness of fit for the following frequency distributions, total 338 and degrees of freedom 8

	0	1	2	3	4
Actual frequencies	15,	38,	76,	70,	64,
Theoretical	8.2,	32,	61.5,	80,	77.7,
	5	6	7	8	9
Actual	53,	31,	19,	14,	20
	60.5,	39.2,	22,	10.6,	7.3

Sol — χ^2 is greater than ψ^2 in the table for 8 degrees of freedom, and so probability is very small that the

series is a bad fit to the observed distribution. Tables exist giving χ^2 for different values of probability P. Generally if P is less than the selected fiducial limit of '05 or of '01, the hypothesis is said to be false

14. Given the following Actual and theoretical Normal frequencies (total 400) Test the goodness of fit (degrees of freedom 10)

Actual	4	11	17	29	43	56
theoretical	4.6,	7.0,	16.8,	30.3,	44.7,	59.1,
	58	63	61	25	20	9
	65,	60.4,	47.5,	31.16,	18.25,	8.8
	4					
	5.3,					

Ans Good

15. The table given below shows the data obtained during an epidemic of cholera

	<i>Attacked</i>	<i>Not Attacked</i>	<i>Total</i>
Inoculated	31	469	500
Not Inoculated	185	1315	1500
	<u>216</u>	<u>1784</u>	<u>2000</u>

Test the effectiveness of inoculation in preventing the attack of cholera.

[Five per cent value of χ^2 for one degree of freedom 3.84]

(Indian Audit and Accounts Service 1941)

Ans Significant

16 Discuss the resemblance of stature of parent and offspring from the following —

Offspring	Parent				Total
	Very Tall	Tall	Medium	Short	
Very Tall	20	30	20	2	72
Tall	14	125	85	12	236
Medium	3	140	165	125	433
Short	3	37	68	151	259
Total	40	332	338	290	1000

(I C S 1936) Ans Great.

17 The following table shows the association, among 1000 school boys, between their general ability and their mathematical ability. Calculate the coefficient of contingency between the two

		General ability		
Math ability		Good	Fair	Poor
	Good	44	22	4
	Fair	265	257	178
	Poor	41	91	98

U A (Maths 1945)

Ans $\psi^2 = 68.8$ $C = 24$

18 In an experiment on the immunization of μ from anthrax the following results were obtained. Derive your inference on the efficacy of the vaccine

	Died of anthrax	Survived
Inoculated with vaccine	2	10
Not inoculated	6	6

(Indian Audit & Accts 1943)

19. The following table gives the results of a series of controlled experiments. Discuss whether the treatment may be considered to have any positive effect.

	Positive	No effect	Negative
Treatment	9	2	1
Control	3	6	3
Total	2	8	4=24

(Indian Audit 1944)

20. The table below shows the data obtained during an epidemic of cholera.

	Attacked	Not attacked
Inoculated	30	470
Not inoculated	185	315

Test the effectiveness of inoculation in preventing the attack of cholera.

(C. St 1945)

21. Explain the use of the Tests of significance and of association in the analyses of commercial data.

(M Com 1946)

CHAPTER XIV

CORRELATION RATIO PARTIAL AND MULTIPLE CORRELATION

The methods of measuring correlation described hitherto are useful when the regressions of the two variables on each other are linear. If regression is non linear the degree of association is measured by means of the Correlation Ratio.

There are two Correlation ratios for each pair of variables x and y explained below

Let n_p = the number of y s in any																																					
array x_p																																					
y_p is any y in array x_p																																					
\bar{y}_p the mean of y s in any																																					
array x_p																																					
	<table> <tr> <td></td> <td>x</td> <td>x</td> </tr> <tr> <td></td> <td>p</td> <td>q</td> </tr> <tr> <td></td> <td>-----</td> <td>-----</td> </tr> <tr> <td>y</td> <td>y</td> <td></td> </tr> <tr> <td></td> <td>p</td> <td></td> </tr> <tr> <td></td> <td>-----</td> <td></td> </tr> <tr> <td></td> <td></td> <td>y</td> </tr> <tr> <td></td> <td></td> <td>q</td> </tr> <tr> <td></td> <td></td> <td>-----</td> </tr> <tr> <td></td> <td>n</td> <td></td> </tr> <tr> <td></td> <td>p</td> <td></td> </tr> <tr> <td></td> <td>-----</td> <td></td> </tr> </table>		x	x		p	q		-----	-----	y	y			p			-----				y			q			-----		n			p			-----	
	x	x																																			
	p	q																																			
	-----	-----																																			
y	y																																				
	p																																				

		y																																			
		q																																			

	n																																				
	p																																				

\bar{y} the mean of all the y 's σ_y^2 the variance of y 's

array x_p

σ_y^2 the variance of all the y 's

$$\text{then the Correlation Ratio } r_{xy}^2 = \frac{\sum \frac{n_p (y_p - \bar{y})^2}{n \sigma_y^2}}{3}$$

where n is the total number of frequencies for the whole distribution.

$$\text{Similarly } \eta^2_{x_y} = \frac{\sum \frac{\{n_{p'}(x_{p'} - \bar{x})^2\}}{n \sigma^2_x}}$$

For application of it see Exercise No. 1

Correlation Ratios, in fact, the ratio between the standard deviation of the means of arrays and the standard deviation of the whole sample and is chiefly used when the data are numerous and can be arrayed in the form of a *Correlation Table*

In finding $\eta^2_{y_x}$, the numerical values of x variates are not used, hence it is possible to find correlation ratio when only one set of variates is quantitative, the others may be attributes such as eye colour, intellectual qualities. The coefficient of correlation r , cannot be found when one variate is qualitative, for that we must have both quantitative. High correlation is associated with values of η approaching unity

When the frequency distribution is normal the correlation ratio is identical with the correlation coefficient r

$$\text{The Standard Error of } \eta \text{ is } \frac{1 - \eta^2}{\sqrt{n}}$$

Partial Correlation—Sometimes it may be desired to measure the relationship between the independent and the dependent with the effect of other independent variables held constant or eliminated. Two variables x and y are correlated partly on account of the fact that each of them is

correlated with a third variable z . We may be required to find the correlation between x and y , quite apart from the influence of z . This is done by the method of partial correlation for instance, yield of a crop of cereals depends partly on rainfall partly on sunshine and other conditions. The relationship between yield and rainfall can be worked out keeping other condition constant.

The correlation between x and y with the effect of z unchanged or ignored, is given by the coefficient of partial correlation (of first order)

$$r_{xy.z} = \frac{r_{xz} - r_{xz} r_{yz}}{\sqrt{1-r_{xz}^2} \sqrt{1-r_{yz}^2}}$$

$$\text{Or briefly } r_{1.3} = \frac{r_{12} - r_{13} r_{23}}{\sqrt{1-r_{13}^2} \sqrt{1-r_{23}^2}}$$

Where $r_{xy.z}$ means the correlation between x and y , z being constant, r_{xy} is the correlation between x and y , r_{xz} between x and z , r_{yz} between y and z .

If there are four variables, the coefficient of 2nd order is (keeping z and u constant)

$$r_{xy.zu} = \frac{r_{xy.z} - r_{xu.z} r_{yz}}{\sqrt{1-r_{xu.z}^2} \sqrt{1-r_{yz}^2}}$$

$$\text{Or briefly } r_{12.34} = \frac{r_{12.3} - r_{14.3} r_{24.3}}{\sqrt{1-r_{14.3}^2} \sqrt{1-r_{24.3}^2}}$$

In this way we can proceed to several variables

Example—Three tests in mathematics were given to a group of students and three sets of scores were correlated with each other, giving $r_{xy} = .6$, $r_{xz} = .5$, $r_{yz} = .4$.

What is the correlation between first and second keeping the third constant?

$$r_{xy \cdot z} = \frac{6 - 5 \times .4}{\sqrt{1 - .25} \sqrt{1 - .16}} = \frac{4}{.79} = .5.$$

Multiple Correlation—In simple correlation we dealt with the relationship between the dependent variable and a single independent variable.

Multiple Correlation is a measure of the combined effect of two or more independent variables upon one dependent variable. For instance, the simple coefficient of correlation between rainfall during a certain period and yield of corn is less than 1. This clearly indicates that some other factor and factors must be taken into account if we want to measure the effect of all the independents upon the yield of corn. The coefficient of multiple correlation is a numerical expression of the extent to which one dependent variable is related to or influenced by the joint or total effect of two or more factors. Multiple Correlation is also known as multivariate correlation, just as simple correlation is called bivariate correlation.

Let $\sigma_1, \sigma_2, \sigma_3, \sigma_4$ denote the standard deviations of the variables or characters 1, 2, 3, 4, (x_1, x_2, x_3, x_4 , say) then $\sigma_{1 \cdot 2}$ is the standard deviation of first one character x_1 when the influence of second x_2 is kept constant, $\sigma_{1 \cdot 23}$ the

S deviation of first when the influence of 2nd and 3rd x_2 and x_3 is kept constant

$$\sigma_{1.2} = \sigma_1 \sqrt{1 - r_{12}^2} \quad \sigma_{1.23} = \sigma_1 \sqrt{1 - r_{12}^2} \sqrt{1 - r_{1.2.3}^2}$$

$$= \sigma_1 \sqrt{1 - r_{12}^2} \sqrt{1 - r_{13.2}^2}$$

$$\sigma_{1.234} = \sigma_1 \sqrt{1 - r_{12}^2} \sqrt{1 - r_{13.2}^2} \sqrt{1 - r_{1.23.4}^2}$$

$$\sigma_{1.234} = \sigma_1 \sqrt{1 - r_{12}^2} \sqrt{1 - r_{13.2}^2} \sqrt{1 - r_{14.23}^2}$$

$$\sqrt{1 - r_{1.234}^2} \quad (n-1)$$

Similarly other standard deviations can be written by analogy such as

$$\sigma_{2.1} = \sigma_2 \sqrt{1 - r_{21}^2} \sqrt{1 - r_{21.3}^2}$$

The standard error of an estimate of x from a regression equation is $\sigma_{1.234}$

The co efficient of multiple correlation is given by

$$R_{1.23}^2 = 1 - \frac{\sigma_{1.23}^2}{\sigma_1^2}$$

Where $R_{1.23}$ is the co efficient of the character (1) with the character 2 3 4

Exercise XIII

1 ~ Find the correlation Ratio for the following table (Dawson)

	11	10	9	8	7	6	5	4	3	2	1
6	4	1									
5	18	6	1								
4	27	14	5	1

130-140			2	3	2	..	1			
120-130	1		1	1						

Total of frequencies=339.

Ans .6 nearly.

III—Given the following: r between supply and price of a commodity = -.9, r between exports and price = -.75, r between supply and exports = .6. Calculate the net relationship between supply and price with the effect of exports held constant.

Ans -.8

IV.—Given the following correlations for intelligence tests, of 200 students, $r_{1a} = .41$, $r_{1s} = .71$, $r_{as} = .5$ where 1 denotes intelligence test score, a , age, s , scholar-achievement.

Find $r_{1s.a}$, $r_{1a.s}$, $r_{as.1}$ and their Probable Errors

Ans. .63, .09, .32

Hint.—Probable errors are found in the same way for simple r

V.—Given, $r_{113} = -.34$, $r_{113}^2 = -.43$, $r_{213} = .187$; $r_{112} = -.43$, $r_{132} = -.62$, $r_{342} = .2$ find the values of $r_{12.34}$, $r_{14.23}$ (approx.) (answers in all the questions are approximate in decimals)

Ans. $-.29$ and $-.4$

VI.—The Correlation between the intelligence-ratios and height of 406 students was .24, that between their age and height was .85 and the correlation between the age intelligence-ratio was .007. Taking height as 1, age 3, intelligence-ratio 2 $\sigma_1 = 15.22$, find the standard error of estimate and co-efficient of multiple Correlation

Sol.—First of all find the partial no efficiencies.

Which are $r_{123} = .46$, $r_{231} = -.415$, $r_{122} = .88$, then $\sigma_{1.23} = 6.9$, $R^2 = .97$ and $R = .98$

VII.—Given $\sigma_1 = 44.7$; $r_{12} = -.5$, $r_{132} = -.62$, $r_{34.23} = -.405$ find $\sigma_{1.234}$ and R

Ans. 41.3 and .78.

VIII.—For three Variables given $\sigma_1 = 17$, $\sigma_2 = 13$, $\sigma_3 = 31$, $r_{12} = -.65$, $r_{13} = -.13$, $r_{23} = .6$ Calculate the Co-efficient $R_{1.23}$, $R_{12.3}$ and $R_{3.12}$

Ans. .75, .85, .47

IX—Given for three agricultural products $r_{12}=.24$, $r_{13}=.85$ $r_{23}=.07$ $\sigma_1=15.2$ determine $R_{1/23}$ (C st 1945)
Hint see Ex VI

X—Find the Regression equations for Q VIII.

Sol—The regression equations will be for 3 variables,

x_1, x_2 and x_3 $x_1 = b_{12.3} x_2 + b_{13.2} x_3$

where $b_{12.3} = r_{12.3} \frac{\sigma_1}{\sigma_2}$ etc

$x_2 = b_{23.1} x_3 + b_{21.3} x_1$ $x_3 = b_{31.2} x_1 + b_{32.1} x_2$

Ans $x_1 = -1.2 x_2 + 2.3 x_3$ $x_2 = -.44 x_1 + 2 x_3$,

$x_3 = .84 x_1 + 2.2 x_2$

CHAPTER XV

MATHEMATICAL THEORY OF INTERPOLATION

We have already explained Interpolation and its method of calculation in Chapter XII

In this chapter mathematical proofs will be given

Symbolic operators The Interpolation formulæ can be expressed in terms of operators Δ , and E , defined as follows for a function $f(a+xw)$ with equal intervals w

$\Delta f(a) = f(a+w) - f(a)$, known as the first difference of $f(a)$

$$\begin{aligned}\Delta^2 f(a+w) &= \Delta f(a+w) - \Delta f(a) \\ &= f(a+2w) - f(a+w) \\ &\quad - \{f(a+w) - f(a)\} \\ &= f(a+2w) - 2f(a+w) + f(a)\end{aligned}$$

known as the second difference

$\Delta^3 f(a+w) = \Delta^2 f(a+w) - \Delta^2 f(a) - \Delta^2 f(a)$ and so on

Difference Table—The differences are arranged in the

$$= f(a+nw) - nf(a+nw-w) + \frac{n(n-1)}{2!} f(a+nw-2w) - \frac{n(n-1)(n-2)}{3!} f(a+nw-3w) + \dots + (-1)^n f(a)$$

Again since

$f(a+xw) = E^x f(a) = (1 + \Delta)^x f(a)$ we have after expanding as binomial

$$f(a+xw) = f(a) + x \Delta f(a) + \frac{x(x-1)}{2} \Delta^2 f(a) + \frac{x(x-1)(x-2)}{3!} \Delta^3 f(a) + \dots - \Delta^n f(a)$$

which expresses the function terms of $f(a)$ and the successive differences of $f(a)$

It is customary to denote $n C_r$ as $\binom{n}{r}$

Example To express $\Delta^3 f(a)$ in terms of the functions and $f(a+3w)$ in terms of successive differences. $\Delta^3 f(a) = f(a+3w) - 3f(a+2w) + 3f(a+w) - f(a)$

$f(a+3w)$ in terms of $f(a)$ and successive differences can be written as $f(a+3w) = f(a) + 3\Delta f(a) + 3\Delta^2 f(a) + \Delta^3 f(a)$ which can be verified directly by the definition of Δ , Δ^2 , and Δ^3

If a function is in the form u then $\Delta u = u$
 $r, w=1 \quad x \quad x+1$

$$-x^u \in g, \Delta x^3 = (x+1)^3 - x^3.$$

$$\Delta^2 u = \Delta u - \Delta u \text{ and so on}$$

$$x \quad x+1 \quad x$$

Differences of a Polynomial and factorial Polynomials

Theorem If there is a polynomial of n th degree, prove that n th differences are constant and $(n+1)$ th differences zero

Proof Consider the polynomial

$$f(x) = Ax^n + Bx^{n-1} + Cx^{n-2} + \dots + K$$

$$\Delta f(a) = f(a+w) - f(a)$$

$$= A\{(a+w)^n - a^n\} + B\{(a+w)^{n-1} - a^{n-1}\} + \dots \quad (1)$$

Using the Binomial theorem,

$$(a+w)^n = a^n + nwa^{n-1} + (n_2)w^2a^{n-2} + \dots$$

From (1)

$\Delta f(a) = A(nwa^{n-1} + n_2w^2a^{n-2} + \dots + w^n) + B(n-1)wa^{n-2} + \dots$ which is a polynomial of degree $(n-1)$ in a . The first differences of a polynomial thus represent another polynomial of degree less by one. Proceeding in this way we derive that r th differences represent a polynomial of degree $(n-r)$ or are constant and the $(n+1)$ th differences are zero.

The polynomial $x(x-1)(x-2)\dots(x-r+1)$ is denoted by $[x]^r$ or $x^{(r)}$ and may be called factorial polynomial.

$$\text{Thus } [a]^r = a(a-1)(a-2)\dots(a-r+1).$$

$$[a+1]^r = (a+1)a(a-1)(a-2)\dots(a-r+3)(a-r+2)$$

$$\begin{aligned} \Delta[a]^r &= [a+1]^r - [a]^r \\ &= a(a-1)(a-2)\dots(a-r+2)\{a+1-(a-r+1)\} \\ &= r[a]^{r-1} \end{aligned}$$

Or in general $\Delta[x]^n = n[x]^{n-1}$ which corresponds to

$$\frac{d}{dx}x^n = nx^{n-1} \text{ in differential calculus}$$

Theorem Show that every polynomial can be expressed in terms of factorial polynomials.

Proof Let $f_n(x)$ be a polynomial of n th degree. Dividing by x , $f_n(x) = a_0 + [x]f_{n-1}(x)$ where $f_{n-1}(x)$ is a polynomial of degree $(n-1)$.

Dividing further by $x-1, x-2, \dots, x-3$ We shall obtain the required result.

$$f(x) = a_0 + a_1[x]f(x) + a_2[x]^2f(x) + \dots$$

Example Express $y = 2x^3 - x^2 + 3x - 1$ in factorial notation

Dividing by x

$$y = (2x^2 - x + 3)[x] + 1$$

$$\begin{aligned} \text{Dividing further by } x-1 \quad y &= 1 + (2x+1)x(x-1) + 4x \\ &= 1 + (2x+1)[x]^2 + 4[x] \end{aligned}$$

$$\text{Dividing by } (x-2) \quad y = 1 + 4[x] + 5[x]^2 + 2[x]^3$$

$$\Delta f(x) = 4 + 10[x] + 6[x]^2$$

$$\Delta^2 f(x) = 10 + 12x$$

$$\Delta^3 f(x) = 12$$

$$\Delta^4 f(x) = 0$$

Proof of Newton's formula for equal intervals. Let be one of the tabulated values of the argument of a polynomial of degree n

The polynomial $f(a+xw)$ can be written as $f(a+xw) = a_0 + a_1[x] + a_2[x]^2 + a_3[x]^3 + \dots + a_n[x]^n$

Differencing,

$$\Delta f(a+xw) = a_1 + 2a_2[x] + 3a_3[x]^2 + 4a_4[x]^3 + \dots$$

$$\Delta^2 f(a+xw) = 2a_2 + 2 \cdot 3 a_3[x] + 4 \cdot 3 a_4[x]^2 + \dots$$

$$\Delta^3 f(a+xw) = 2 \cdot 3 a_3 + 4 \cdot 3 \cdot 2 a_4[x] + \dots$$

The value of the coefficients a_0, a_1, a_2

will be determined by putting $x=0$ in the above

$$\text{Thus } a_0 = f(a)$$

$$a_1 = \Delta f(a)$$

$$a_2 = \frac{\Delta^2 f(a)}{2!}$$

$$a_3 = \frac{\Delta^3 f(a)}{3!}$$

$$a_4 = \frac{\Delta^4 f(a)}{4!}$$

$$a_n = \frac{\Delta^n f(a)}{n!}$$

$$f(a+xw) = f(a) + x\Delta_1(a) + \frac{x(x-1)}{2!}\Delta^2 f(a) + \frac{x(x-1)(x-2)}{3!}\Delta^3 f(a) + \dots$$

This is known as Gregory Newton formula or simply Newton formula of interpolation which is used for interpolation and can be represented geometrically as a straight line or a curve

For examples in Newton's formula see Chapter VII and Exercise XI

Divided Differences and Newton's formula for unequal intervals

Let a, b, c, d be arguments at unequal intervals and $f(a), f(b), f(c)$ — the corresponding functions

The divided difference of the first order is defined by

$$f(a, b) = [ab] = \frac{f(a)}{a-b} + \frac{f(b)}{b-a} = \frac{f(a) - f(b)}{a-b}$$

The divided difference of second order is defined by

$$f(a, b, c) = \frac{f(a)}{(a-b)(a-c)} + \frac{f(b)}{(b-a)(b-c)} + \frac{f(c)}{(c-a)(c-b)} \\ = \frac{f(ab) - f(bc)}{a-c}$$

$$f(a, b, c, d) = \frac{f(a)}{(a-b)(a-c)(a-d)} + \frac{f(b)}{(b-a)(b-c)(b-d)} \\ + \frac{f(c)}{(c-a)(c-b)(c-d)} + \frac{f(d)}{(d-a)(d-b)(d-c)} = \frac{f(abc) - f(bcd)}{a-d}$$

Similarly the divided differences of higher order can be defined

Newton's formula for unequal intervals

Let $f(x)$ be a function whose divided differences of order n are zero or so small as to be neglected, such that the n th order differences are constant. The table of divided

$$\begin{array}{l}
 a \{ f(a) \\
 b \{ f(b) \quad f(ab) f(abc) f(abcd) \quad f(abcde) \\
 c \{ f(c) \quad f(bc) f(bcd) f(bcde) \\
 d \{ f(d) \quad f(cd) f(cde) \\
 e \{ f(e) \quad f(de)
 \end{array}$$

The problem is to find the value of the function for other argument u , which may or may not be contained in the above arguments,

Since the divided differences of third order are constant

$$\therefore f(abcd) = f(uabc)$$

It is known that

$$f(uabc) = \frac{f(uab) - f(abc)}{u - c} = f(abcd)$$

$$\therefore f(uab) = f(abc) + (u - c)f(abcd)$$

$$\text{Also } f(uab) = [f(uc) - f(ab)] \frac{1}{u - b}$$

$$\therefore f(u) = f(ab) + (u - b)\{f(abc) + (u - c)f(abcd)\}$$

$$\text{But } f(ua) = \frac{f(u) - f(a)}{u - a}$$

$$\begin{aligned}
 \therefore f(u) &= (u - a)f(ua) + f(a) \\
 &= f(a) + (u - a)f(ab) \\
 &\quad + (u - a)(u - b)f(abc) + (u - a)(u - b)(u - c)f(abcd)
 \end{aligned}$$

The formula holds in general when the differences of order $(n+1)$ are zero or negligible and is known as Newton's formula for unequal intervals

Lagrange's formula of interpolation

Let $f(x)$ be polynomial of degree n which for values $a_0, a_1, a_2, \dots, a_n$ of x possess the values $f(a_0), f(a_1), \dots, f(a_n)$ respectively

The divided differences of order n of a polynomial are constant, since the divided differences of order n of each of the terms whose degree is less than n is zero. The divided differences of order $(n+1)$ will be zero.

The divided differences of $(n+1)$ th order, by definition
 s given by $f(x, a_0, a_1, a_2, \dots, a_n)$

$$= \frac{f(x)}{(x-a_0)(x-a_1)\dots(x-a_n)} \\
+ \frac{f(a_0)}{(a_0-x)(a_0-a_1)\dots(a_0-a_n)} \\
+ \frac{f(a_1)}{(a_1-x)(a_1-a_0)\dots(a_1-a_n)} + \dots \\
+ \frac{f(a_n)}{(a_n-x)(a_n-a_0)\dots(a_n-a_{n-1})} = 0$$

Which gives on multiplication throughout by
 $(x-a_0)(x-a_1)\dots(x-a_n)$
 and simplifying

$$f(x) = \frac{(x-a_1)(x-a_2)\dots(x-a_n)}{(a_0-a_1)(a_0-a_2)\dots(a_0-a_n)} f(a_0) \\
+ \frac{(x-a_0)(x-a_2)\dots(x-a_n)}{(a_1-a_0)(a_1-a_2)\dots(a_1-a_n)} f(a_1) \\
+ \frac{(x-a_0)(x-a_1)(x-a_3)\dots(x-a_n)}{(a_2-a_0)(a_2-a_1)\dots(a_2-a_n)} f(a_2) + \dots$$

Which is Lagrange's formula of interpolation of for unequal intervals

For illustration see chapter XII article 2.

Central difference formulae of Interpolation

In the central difference formulae, the argument x is taken the centre or near about the centre of the arguments as

Arguments	Functions
$x-2w$	$u_{-2} = f(x-2w)$
$x-w$	$u_{-1} = f(x-w)$
x	$u_0 = f(x)$
$x+w$	$u_1 = f(x+w)$
$x+2w$	u_2

A Notation δ is used according to which $\delta = \Delta E^{-\frac{1}{2}}$ or
 $= \delta E^{\frac{1}{2}}$ Thus $\Delta u_0 = \delta u_{\frac{1}{2}}$, $\Delta^2 u_0 = \delta^2 u_1$

The following are the well known formula in Central differences, which will be proved

Newton Gauss formula, known as Gauss formula

Newton Stirling's formula Bessel's and Everett's formulae Gauss formula

Let the function $f(a+xw)$ have the arguments $a-3w$, $a-2w$, $a-w$, $a+w$, $a+2w$ In Newton's formula for unequal intervals, write

$u = a+xw$, $b = a+w$, $c = a-w$, $d = a+2w$, $e = a-2w$ and so on

$\therefore f(a+xw) = f(a) + xw f(a, a+w) + xw(a+xw-a-w) f(a, a+w, a-w) +$

$$\text{But } f(a, a+w) = \frac{f(a+w) - f(a)}{w} = \frac{1}{w} \Delta f(a)$$

$$f(a, a+w, a-w) = \frac{\Delta^2}{2! w^2} f(a-w)$$

$$f(a, a+w, a-w, a+2w) = \frac{1}{3! w^3} \Delta^3 f(a-w) \text{ and so on}$$

Hence

$$\begin{aligned} f(a+xw) &= f(a) + x \Delta f(a) + \frac{x(x-1)}{2!} \Delta^2 f(a-w) \\ &+ \frac{(x+1)x(x-1)}{3!} \Delta^3 f(a-w) \\ &+ \frac{(x+1)x(x-1)(x-2)}{4!} \Delta^4 f(a-2w) \\ &+ \frac{(x+1)x(x-1)(x-2)}{5!} \Delta^5 f(a-2w) + \dots \end{aligned} \quad \text{which is}$$

Gauss formula

Newton Stirling's formula

In Gauss formula, the terms may be arranged as

$$f(a+xw) = f(a) + x [\Delta f(a) - \frac{1}{2} \Delta^2 f(a-w)]$$

$$+ \frac{x^2}{2!} \Delta^2 f(a-w) + \frac{x(x^2-1^2)}{3!} [\Delta^3 f(a-w) - \frac{1}{2} \Delta^4 f(a-2w)] \\ + \frac{x^2(x^2-1^2)}{4!} \Delta^4 f(a-2w) +$$

Replace the differences of even order in square brackets by the differences of odd order using the relations,

$$\Delta^2 f(a-w) = \Delta f(a) - \Delta f(a-w)$$

$$\Delta^4 f(a-2w) = \Delta^3 f(a-w) - \Delta^3 f(a-2w)$$

Substituting we obtain Stirling's formula in the form

$$f(a+xw) = f(a) + x \left\{ \frac{\Delta f(a) + \Delta f(a-w)}{2} \right\}$$

$$+ \frac{x}{2!} \Delta^2 f(a-w)$$

$$+ \frac{x(x^2-1^2)}{3!} \left\{ \frac{\Delta^3 f(a-w) + \Delta^3 f(a-2w)}{2} \right\}$$

$$+ \frac{x^2(x^2-1^2)}{4!} \Delta^4 f(a-2w) +$$

Newton Bessel's formula

Gauss' formula can be written as

$$f(a+xw) = \frac{1}{2} f(a) + \frac{1}{2} f(a) + x \Delta f(a)$$

$$+ \frac{x(x-1)}{2!} \left(\frac{1}{2} \Delta^2 f(a-w) + \frac{1}{2} \Delta^2 f(a-w) \right)$$

$$+ \frac{(x+1)x(x-1)}{6} \Delta^3 f(a-w) +$$

Substituting the values of $\frac{1}{2} f(a)$, $\frac{1}{2} \Delta^2 f(a-w)$, $\frac{1}{2} \Delta^4 f(a-2w)$ from the relations $\Delta f(a) = f(a+w) - f(a)$

$$\Delta^2 f(a-w) = \Delta^2 f(a) - \Delta^3 f(a-w)$$

$$\Delta^4 f(a-2w) = \Delta^4 f(a-w) - \Delta^5 f(a-2w) \quad \dots$$

In Gauss formula, written above the result is,

$$f(a+xw) = \frac{1}{2} \{f(a+w) - \Delta f(a)\} + \frac{1}{2} f(a)$$

$$+ x \Delta f(a) + \frac{x(x-1)}{2!} \frac{1}{2} \{ \Delta^2 f(a) - \Delta^3 f(a-w) \}$$

$$+ \frac{x(x-1)}{2!} \frac{1}{2} \Delta^3 f(a-w) + \dots$$

Rearranging we obtain Bessel's formula as

$$\begin{aligned} f(a+xw) &= \frac{1}{2} \{f(a) + f(a+w)\} \\ &+ (x - \frac{1}{2}) \Delta f(a) + \frac{x(x-1)}{2!} \frac{1}{2} \{ \Delta^2 f(a-w) + \Delta^2 f(a) \} \\ &+ \frac{x(x-1)}{3!} (x - \frac{1}{2}) \Delta^3 f(a-w) + \dots \end{aligned}$$

Laplace-Everett's formula.

From Gauss formula

$$\begin{aligned} f(a+xw) &= f(a) + x \Delta f(a) + (x_2) \Delta^2 f(a-w) \\ &+ (x+1_3) \Delta^3 f(a-w) + (x+1_4) \Delta^4 f(a-2w) + \dots \end{aligned}$$

Eliminate the differences of odd order, using

$$\begin{aligned} \Delta f(a) &= f(a+w) - f(a) \\ \Delta^3 f(a-w) &= \Delta^3 f(a) - \Delta^3 f(a-w), \dots \end{aligned}$$

We obtain

$$\begin{aligned} f(a+xw) &= f(a) + x \{f(a+w) - f(a)\} + (x_2) \Delta^2 f(a-w) \\ &+ (x+1_3) [\Delta^3 f(a) - \Delta^3 f(a-w)] + (x+1_4) \Delta^4 f(a-2w) \end{aligned}$$

Applying the general result, $n+1C_r = nC_r + nC_{r+1}$

$${}^{n+1}C_{r+1} = {}^nC_{r+1} + {}^nC_r$$

$$\begin{aligned} f(a+xw) &= f(a) [1-x] + xf(a+w) \\ &+ (x+1_3) \Delta^2 f(a) - (x_3) \Delta^3 f(a-w) \\ &+ (x+2_5) \Delta^4 f(a-w) - (x+1_5) \Delta^5 f(a-2w) + \dots \end{aligned}$$

Transforming the Coefficients of $f(a)$ by $1-x=\eta$, the result can be written in central difference notation as

$$\begin{aligned} f(a+u) &= {}_r u = \left[\eta + \frac{\eta(\eta^2-1)}{3!} \delta^2 + \dots \right] u_0 \\ &+ \left[x + \frac{x(x^2-1)}{3!} \delta^2 + \dots \right] u_1 \end{aligned}$$

Which is Everett's formula used for interpolating $f(a)$ and $f(a+w)$.

EXERCISE XIV

1 Find the value of $\Delta^3 u$ and express $f(x+6w)$ in terms of (a) and its differences

$$\text{Ans } u = (3)_1 u + 3u - u \\ x+3 \quad x+2 \quad x+1 \quad x$$

2 Prove that the $(n+1)$ th difference of a polynomial of n th degree vanish. Represent the function $x^4 - 127x^3 + 42x^2 - 30x + 9$ into factorial and show that the fourth difference is 24

(M A Aligarh 1943)

3 Let a, b, c and d be successive entries in a difference table corresponding to equidistant arguments show that when fourth and higher differences are neglected the entry corresponding to the argument half way between the arguments of

$$\text{and } c \text{ is } \frac{9(b+c) - (a+d)}{16}$$

$$\begin{aligned} 4 \text{ Given } \log \tan 24^\circ &= 0.64858 \quad \log \tan 24^\circ 20' \\ &= 9.648696 \quad \log \tan 24^\circ 40' = 9.648923 \quad \log \tan 24^\circ 1' \\ &= 9.64892 \quad \log \tan 24^\circ 1' 20'' = 9.64903 \end{aligned}$$

$$\text{Find the value of } \log \tan 24^\circ 5' \quad \text{Ans } 9.64861$$

$$\begin{aligned} 5 \text{ Given } \log 6.04 &= 78103 \quad \log 6.041 = 7811 \quad \log 6.042 = 78118 \\ \log 6.043 &= 78125 \quad \log 6.044 = 78132 \quad \text{deter-} \\ \text{mine the value of } \log 6.0104 & \quad \text{Ans } 78106 \end{aligned}$$

$$6 \text{ Show that (1) } f(abcd) = \frac{f(abc) - f(bcd)}{a - d}$$

(2) The divided differences of order n of x^n and that of polynomial of n th degree are constant

7 Establish Lagrange's formula with the help of Alternants

$$\begin{array}{cccccc} 8 \text{ Given } x & 5 & 11 & 27 & 34 & 42 \\ f(x) & 23 & 899 & 17315 & 35606 & 68510 \end{array}$$

Express $f(x)$ in terms of the powers of $x-3$

(M A Aligarh 1943)

$$\text{Ans } -13 + 2(x-3) + 6(x-3)^2 + (x-3)^3$$

9 Show that (1) Gregory Newton's formula is a special case of Newton's formula for unequal intervals

(2) The differential operator D can be connected with the difference operator Δ

$$10 \text{ Given } \sqrt{12500} = 111.803399 \quad \sqrt{12510} \\ = 111.84811 \quad \sqrt{12520} = 111.892806, \quad \sqrt{12530} \\ = 111.937483 \text{ show that } \sqrt{12516} = 111.874929$$

(M A Panjab 1943)

$$11 \text{ Given } \sec 88^\circ 4' = 61.3911 \quad \sec 89^\circ 5' = 62.5072 \\ \sec 89^\circ 6' = 63.6646 \quad \sec 89^\circ 7' = 64.8657 \text{ show that } \\ \sec 89^\circ 5' 40'' = 63.274'$$

(M A 1944)

$$12 \text{ Show that } f(a+w, a-w) = \frac{1}{2w^2} \Delta^2 f(a-w)$$

$$f(a+w, a-w, a+2w) = \frac{1}{3!w^3} \Delta^3 f(a-w)$$

$$f(a-w, a+w, a-2w) = \frac{1}{3!w^3} \Delta^3 f(a-2w)$$

13 Deduce Gauss Backward formula from Newton's formula for unequal intervals i.e.

$$f(a-xw) = f(a) - x \Delta f(a-w) \\ + \frac{x(x-1)}{2!} \Delta^2 f(a-w) +$$

14 Show how Newton's formula and Stirling's formula can be applied to find the values of the differential coefficients of a given function

15 Express the derivatives of $f(x)$ in terms of the divided differences

16 What is subabulation? Derive the formulae for subabulation with the help of Gregory Newton formula

17 Given the following values obtain the value of $f(x)$ when $x=4$

x	30	35	40	45	50	55	60
$f(x)$	771	862	1001	1224	1572	2123	2883

(M. A. 1945) Ans 1081 873.

18. Find the form of the function given that $f(0)=8$
 $f(1)=11$ $f'(4)=68$, $f(5)=128$ — (M. A. 1945).

Ans $5x^3 - 9x^2 + 16x + 32$.

19. Given, $\sin 25^\circ 40' = 43311$, $\sin 25^\circ 40' 20'' = 43322$, $\sin 25^\circ 40' 40'' = 43336$ $\sin 25^\circ 41' = 43339$, $\sin 25^\circ 41' 20'' = 43348$, find the value of $\sin 25^\circ 40' 30''$ by Stirling and Bessel formulæ

Ans. 43326.

20. Given, Logarithms of $310=2.4914$, $320=2.5051$, $330=2.5185$, $340=2.5315$, $350=2.544$, $360=2.5563$, apply any central difference formula to find $\log 349$ and $\log 3375$.

Ans 2.5428, 3.5928

21. Given the following values for $y=\log_e x$ at $x=300$, 301 , 302 , 303 , 304 , 305 , 306 , 307 , 5.7037 , 5.7071 , 5.7104 ,

5.7137 , 5.7170 , 5.7203 , 5.7235 , 5.7268 , find the values of $\frac{dy}{dx}$ at $x=300$ and 302

Ans. .0033, .00331.

Hint—Differentiate Newton's formula

22. Given, $\sin 25^\circ = 4226$, $\sin 25^\circ 1' = 4229$,
 $\sin 25^\circ 2' = 4231$ Subtabulate for $\sin 25^\circ 20''$ and $40''$

Ans .42271, .42281.

23. A root of $x^3 + x = 3$ lies between 1.2 and 1.3. Find by inverse interpolation its value upto four places of decimals

Ans. 1.2134.

24. Show that if $w = u \frac{x}{x+0} + u \frac{x}{x+1} + \dots + u \frac{x}{x+(t-1)}$,

then the individual value u may be found from the groups

$$\frac{x}{t}$$

of t individual values w_0, w_1, w_2 , and their differences by the formula

$$u = \frac{w_0}{t} + (2x - t + 1) \frac{\Delta^2 w_0}{2! t^2}$$

$$+ \{3x^2 + 3x(1-2t) + (1-3t+2t^2)\} \frac{\Delta^2 w_0}{3 \cdot t^3}.$$

neglecting higher differences. (Forsyth)

Hence or otherwise find the value of the quantity for the middle year of the second quinquennium from 44133, 41921, 39387
Ans 8387 (nearly)

Sol Put $x=7$ and $t=5$ in the formula

25 The population of a country for four consecutive age groups are given by 10 to 14 years (inclusive) 458572, 15-19, 441424, 20-24, 423123, 25-29, 402918 use formula in Q 10 or (otherwise) to find the populations of ages between 17-18 and 22-23 years
Ans 88294, 84640

26 Prove Euler-Maclaurin formula and apply it to obtain Stirling's approximation to the factorial Explain Bernoulli's numbers (M A Punjab 1942 & 1943.)

Obtain a formula for the sum of n th powers of the first k integers

27 Sum the series

$$(a) \frac{1}{(201)^2} + \frac{1}{(203)^2} + \frac{1}{(205)^2} + \dots + \frac{1}{(296)^2}$$

$$(b) \frac{1}{11^3} + \frac{1}{12^3} + \frac{1}{13^3} + \dots \text{ad inf.}$$

(M.A Punjab, 1942)

Ans (a) 000833 (b) 00452

(c) Derive Lubbock and Gregory formulae for summation (M A. 1944)

28 Explain the method of least squares and describe one of the fundamental methods of solving Normal equations, showing the Mathematical process clearly

(M A Aligarh, 1942)

29 Given $491x - 59y = -3398$, $272x - 27y = -475$, $05x + 324y = 2625$, $-291x + 277y = 1529$, $-477x + 4y = -279$. Form normal equations and find x and y

(M A. Aligarh 1941)

Ans Normal equations are $6273x - 3827y = -20963$
and $-3827x + 53073y = 328777$, $x = 7.81$ and
 $y = 6.76$ (See Chapter VIII, for Normal equations etc)

30 Apply Dooblittle's method to solve the normal equations

$$\begin{aligned} x + 3y - 2z + 0u - 2v &= 5, & 3x + 4y - 5z + u - 3v &= 54, \\ -2x - 5y + 3z - 2u + 2v &= -5, & y - 2z + 5u + 3v &= 75, \\ -2x - 3y + 2z + 3u + 4v &= 33 \end{aligned}$$

Ans 15, -1, 4, 27 -140035

31 State briefly the characteristic properties of Lexian and Bernoullian distributions. Show that the Lexian variance exceeds the Bernoullian one by an amount which increases with n , the number of trials (M A 1943)

32 Prove Euler-Maclaurin formula

$$a + rw$$

$$\frac{1}{w} \int_a^{a+rw} f(x) dx = \frac{1}{2} f(a) + f(a+w) +$$

$$+ \frac{1}{2} f(a+rw) - \frac{w}{12} [f'(a+rw) - f'(a)] +$$

and Compute $\int_{100x}^{105} \frac{dx}{x}$

correctly to seven places of decimals

Ans 0487902 (M A 1943)

33 Describe the important properties of normal distribution, and derive the equation of the normal frequency curve in the form

$$-\frac{x^2}{2\sigma^2}$$

$$y = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{x^2}{2\sigma^2}}$$

State characteristic properties of this curve

_____ (M A 1943 & 1945)

34 Write a short note on the periodogram anal., and derive the equation of the periodogram
(M.A. 1943 & 1945).

35 Explain the meaning of trigonometric interpolation. Determine the co-efficients in the sum

$$a_0 + a_1 \cos x + a_2 \cos 2x + \dots + a_5 \cos 5x + a_6 \cos 6x \\ + b_1 \sin x + b_2 \sin 2x + \dots + b_5 \sin 5x$$

which takes the given values u_0, u_1, \dots, u_{11} respectively if x takes the values

$$0, \frac{\pi}{6}, \frac{2\pi}{6}, \frac{3\pi}{6}, \dots, \frac{11\pi}{6}$$

respectively. [Hint.—This is Fourier analysis, n being 12.]
(M.A. 1943 & 1945)

The co-efficients are given by

$$a_0 = \frac{1}{n} \sum_{p=0}^{n-1} u_p, \quad a_1 = \frac{2}{n} \sum_{p=0}^{n-1} u_p \cos \frac{2p\pi}{n},$$

$$a_r = \frac{2}{n} \sum_{p=0}^{n-1} u_p \cos \frac{2pr\pi}{n},$$

$$b_r = \frac{2}{n} \sum_{p=0}^{n-1} u_p \sin \frac{2pr\pi}{n}$$

when $r = \frac{n}{2}$, use $\frac{1}{n}$, instead of $\frac{2}{n}$ in a_r .

$$\text{Thus for } n=12, a_1 = \frac{1}{6} \left\{ u_0 + u_1 - \frac{\sqrt{3}}{2} u_2 + u_3 - \frac{1}{2} u_4 \right. \\ \left. - \frac{\sqrt{3}}{2} u_5 - u_6 - u_7 + \frac{\sqrt{3}}{2} u_8 - u_9 + \frac{1}{2} u_{10} + \frac{\sqrt{3}}{2} u_{11}, \text{ etc.} \right\} \text{ [Sim}$$

ilarly the co-efficients can be worked out for $n=4$ and $n=6$].

36 Write short notes on —

Bivariate normal frequency surface, mail expectation; Tests of significance, multiple correl., Correlation Ratio, Regression, Dispersion.

(M.A. 1945 & 1947)

CHAPTER XVI

INDIAN STATISTICS

(A) A brief summary of Bowley-Robertson inquiry with regard to

(1) Organisation of Statistics in India

(2) Measurement of National income

(3) Census of Production

(B) List of statistical publications in India will be dealt with in this Chapter

(A) Bowley-Robertson report, entitled 'A scheme for an Economic Census of India' (1934) deals with the fundamental points mentioned above

We shall take up briefly the recommendations of the Bowley-Robertson Committee one by one

1—Organisation of Statistics—A permanent economic staff consisting of four members, one being the Director of Statistics should be established directly attached to the Economic Committee of the Governor General's Executive Council, for the organisation of the whole work of economic intelligence

The duties of the Director of Statistics should include (i) conduct of the census of population (ii) Conduct of the census production, (iii) Co ordination of the central and provincial statistics. The census of production should be quinquennial (after 5 years) and while the main census of population continues to be decennial a supplementary census mainly devoted to numbers, age, sex, and occupation of people should be taken in the middle of the decennium

There should be in each major province a whole time statistician, as nearly independent of departmental control as administrative requirements permit but making his services available to all departments. The Director of Statistics should as far as possible, have contact with the Statistics of the provinces to promote uniformity in the provincial statistics and thus facilitating their assembly into all-India totals

It may be pointed out that following the Committee's

major departments of the central and provincial Governments

II — Measurement of National Income — The authors remark that the materials for estimating the national income in India are very defective and thus they made several practical proposals for the measurement of the total national income in India

'The national income according to the Committee is the money measure of the aggregate of goods and services accruing to the inhabitants of a country during a year, including net increments to or excluding net decrements, from their individual or collective wealth'

Two methods of calculation of the national income have been pointed, first is an evaluation of goods and services accruing and second is a summation of individual incomes

The first method is the 'census of production, method and the second is the 'census of income' method

Both the methods may be employed for the purpose, but special caution in combining the results of the two may be necessary especially in the case of India

The census-of-production method involves,

1 Evaluating the net output of agriculture, mining, industry and other productive enterprises at the point of production Double counting (e.g counting both the output of wheat and the labour of the cattle employed in raising it) should be avoided

All that part of the product of agriculture etc, which is consumed by the producer or bartered locally for the services of workers, should be valued, the price prevailing at the point of production to be counted

2 Adding the value which the transporting and merchanting agencies impart to home produced goods and to imports

3 Adding excise duties on home produced goods and custom duties on imports, in order to secure the aggregate of exchange values to the consumer.

4. Adding the value of imports including gold and silver

- 5 Deducting the value of exports including gold and silver
- 6 Adding the value of personal services of all kinds
- 7 Adding the annual rental value of houses, whether rented or occupied by the owners
- 8 Adding the increments or deducting the decrements of bank balances and securities abroad whether, by individuals or by governments, similarly, deducting the increments or adding the decrements in the holdings of balances and securities in the country by residents abroad.
- 9 Deducting the value of goods, whether home produced or imported, which are used for the purpose of keeping intact the fixed Capital, raw materials or finished commodities

The method of census of production (or products) described above is more fundamental of the two methods of evaluating the national income

Certain precautions would have to be observed so that the result of the census of income method may tally with those of the first

The second method consists of the summation of individual incomes.

Bowley and Robertson make a distinction of rural income and urban income for India

For *rural income* they recommend an estimate of the quantity and value of all goods and services which arise from the land or rendered in the villages, by the method of intensive surveys in selected villages

For urban income, they recommend *surveys of the larger towns* based on a sample inquiry of the personnel and occupations of families, and an estimate of their incomes by personal statements and by investigation of wages and salaries prevailing in the towns. For incomes over at least Rs. 2,000, income tax statistics can be of valuable help. They have recommended an intermediate urban population census.

These three inquiries would be supplemented by a census

of production applied to factories using power, mines and some other industries

All the investigations should be extended to the Indian States so far as they are willing and able to cooperate. For areas not so covered, estimates will be necessary by the use of agricultural statistics

Rural sample Surveys—The statistical method for selecting the villages for intensive survey is that of random sampling which may be applied as—Prepare a complete list of all the villages in a province, arrange them in geographical order of districts (or in an order that corresponds to various types of cultivation), decide on the number of villages to be investigated, and finally, starting from a random number, mark the required number of villages all nearly equally spaced. For example, in a province having 110 000 villages, it is decided to investigate 300 villages

The first mark may be placed on any arbitrary number, say 5th village, on the list, the next mark will be on

$$\left(5 + \frac{110000}{300} \right); \text{ i.e. on 371 village and so on}$$

Thus every unit in the list shall have a chance of being included for inquiry

When the villages have thus been selected, no other should be substituted

The report gives the following table which indicates the proposed minimum number of villages for investigation in each province

Province	Number of villages	Number in Sample
Bengal	86,000	250
Bihar and Orissa	83,000	300
Bombay	21,000	200
Central Provinces	40,000	200
Madras	51 000	200
Punjab	35,000	200
U. P.	106,000	200

To make the total for British India some estimates should be made for Assam, N W F Province, tea plantations of Bengal, areas of Bengal where coal mining is important and the areas affected by earthquake and not fully resettled till the period of inquiry

For conducting the investigations and sample surveys, trained investigators and qualified statisticians should be appointed in order to obtain satisfactory and reliable results

The investigator should live in the village for a year or so

The work of the investigators may be supervised by senior investigators

The entire survey should be under the control of the Director of Statistics at the the centre, through the Provincial statistician

The necessary schedules and Questionnaires should be carefully and briefly drawn considering the local circumstances, and they must have local terms of measures weights etc

Although the main inquiry is to be directed to income, production, consumption and allied topics, the investigator may collect information regarding health, co operation debt etc of the people of the village concerned

Urban Surveys—For urban income, as mentioned before, surveys of the larger towns have been recommended Random sampling is not recommended

As most of the larger towns or cities have University Centre or Colleges, so surveys of such towns should first be conducted Later on, on similar lines, other towns are to be investigated

For the organisation of *University city surveys*, a central committee should be appointed to draw up an outline schedule of enquiry, to advise and present a report on the whole subject at the end In every University and College there will be the Economics Department to help in the conduct of the economic investigation of the towns The staff and the students, backed by official and monetary help

can easily undertake the work of inquiry. The post graduate students having knowledge of or qualification in statistics would prove of good help.

In this way the students will also have practical training. The Education Department of the Province will also be of great assistance in this matter.

When intensive surveys of University and College towns are completed surveys of other towns are to be undertaken and some of the more efficient investigators in the University city surveys be appointed for carrying on the work.

An occupational census is almost essential. For this census enquiries should be made about current rates of earnings and wages estimated over the years and allowing for seasonal fluctuations.

Each industry and occupation of any importance must be included and workers in industries clerks municipal and railway employees tonga drivers and all others working for salaries or wages or making petty profits should be given the same importance. The method of payment may also be recorded.

An accurate list of houses or tenements should be prepared. Big towns containing say nearly 150 000 houses should be subdivided into five units, each having nearly 30 000 houses. About 1 000 houses selected in each unit at random should be visited by the investigator and no house is to be substituted.

The visitor should have friendly relations with the residents in order to obtain reliable information about numbers sex age and occupation of the family groups. Schedules and Questionnaires should be filled in immediately after and not during the visit. Repeated visits may be essential to collect correct data.

The totals should in case of doubt be given varying within a certain range and not as an exact number.

All existing data relating to the subject of the survey should be carefully studied and all persons official and non-official interested in or concerned with the collection of data

should be consulted with a view to have a reliable and serviceable data

III — Census of Production — The census of production would be imposed by special Act of the Legislative Assembly at the Centre, making the communications of facts demanded compulsory. The census would be conducted by the Director of Statistics with the co-operation of the Departments of Industries and Labour.

Industries employing 20 or more persons and using mechanical power, some small workshops, and also some large non mechanical establishments such as brick-making and carpet making industries should be investigated. Railways and all establishments under the mines Act should also be dealt with.

Since the progress of factory industry is, to a certain extent, at the cost of cottage industry, it will be of great value if the two are brought in statistical relation with each other, and if, some annual data about them could be obtained, it will show their relative increase or decrease.

For the purpose of the census, it is essential that the questionnaires be simple and adapted to Indian environments. The essential facts to be elicited are aggregate value of the sales and the aggregate cost of materials for each factory. The difference will approximately indicate the national income according to the factory and when all the factories are taken into account the aggregate differences minus depreciation of plant and change in the value of materials and finished goods will measure the contribution to the national income of the industry.

Details can also be obtained of the amounts and values of different commodities produced, and of material purchased and power used.

The classification of the product should be the same as that of exports and imports. The employees should be classed as salaried persons and wage earners, young and adult with an exact statement of the age-division between males and females.

To get an average for the year and also as an

indication of seasonal variations, it is best to obtain the details of the employees for one week in each month of the year.

The investigators will face opposition and difficulty but with periodic repetition of the census, they will automatically disappear.

B.—List of important statistical publications in India

I Publications of the Department of Commercial Intelligence and Statistics, Government of India.

1. Statistical Abstract for British India (annual)

2. Agricultural Statistics of India —

Vol I—British India (annual)

Vol II—Indian States (annual) .

3. Statistical Tables relating to Banks in India (annual)

4. Statistical Tables relating to the Co-operative Movement in India (annual)

5. Large Industrial Establishments in India

6. Review of the Trade of India (annual)

7. Indian Trade Journal (weekly)

8. Live-Stock Statistics India (quinquennial).

9. Monthly statistics of cotton spinning and weaving in Indian Mills

10. Monthly Statistics of the production of certain selected Industries of India

11. Accounts relating to the Sea-borne Trade and Navigation of British India (monthly)

12. Accounts relating to the Inland (Rail and River-borne) Trade of India (monthly)

13. Monthly statement of wholesale prices of certain selected articles at various centres in India.

14. Accounts relating to the Sea-borne Trade and Navigation of British India (annual)

15. Estimates of area and yield of principal crops in India (annual).

16 Indian tea coal rubber and coffee Statistics published separately) (annual)

17 Joint Stock Companies in British India and in some Indian States (annual)

18 Crop forecasts of Rice Wheat Cotton, Linseed, Sesamum Groundnut Sugar cane Castorseed (Periodically also published in the Indian Trade Journal)

19 Quinquennial Report on the average yield per acre of Principal crops in India

20 Crop Atlas of India

II —Other Government (Official) Publications

1 Gazette of India (weekly,

2 Gazettes of Provinces (also of States weekly)

3 Labour Gazette Bombay (monthly)

4 Central and Provincial Government's budgets (annual)

5 Administration Report of Provincial Governments (annual)

6 Administration report of Railways in India (annual)

7 Census Reports (for India Provinces and States) Decennial

8 Report of the Controller of Currency (annual)

9 Monthly survey of business conditions in India

10 Guide to current official statistics

11 Working class Family Budgets

12 India Labour Gazette Monthly

13 Statistics of Factories issued by the Labour Department of Government of India

14 Nutrition (Food Department)

15 Publication of Imperial Council of Agricultural Research

III —Non official publications and Research Journals

I—QUESTIONNAIRE FORM

BOARD OF ECONOMIC INQUIRY PUNJAB LAHORE

Socio Economic Survey of Greater Lahore

Housing Conditions

- 1 Ward and Locality
- 2 Mohalla Road Street
- 3 Lane (if any) 4 Width of the lane or street
- 5 House No 6 Name of owner
- 7 (a) Owner's religion and nationality Hindu Muslim, Sikh Indian Christian Parsee Anglo Indian, European others (specify)
- 8 (b) Owner's domicile (Province or State)
- 9 Owner's Occupation
- 10 Kind of dwelling: Bungalow house hut
- 11 Nature of dwelling Pacca, kachha temporary structure
- 12 Year in which built
- 13 Number of Storeys (excluding underground accommodation) one two three four five
- 14 Total height of building in feet from ground level

- 13 Number of underground rooms (if any)
How are these rooms used? — — —
14. Total area of land (in marlas or square feet) — —
Area of the open space or courtyard (if any)
How is the open space or courtyard used?
— —
- 15 Total cubic space (in cubic feet) of the covered living
rooms on
Ground floor
1st floor — —
2nd floor — — 3rd floor — —
4th floor — — 5th floor — — Grand total
- 16 Total number of families living
(a) owners (b) tenants Total
- 17 Total number of occupants (exclude visitors
servants living outside the building)
(a) males (b) females Total
- 18 Cubic space per person
- 19 Is there any Electric power connection? Ye no
- 20 Source of water supply Inside the house outside it
If inside, whether Municipal tap, private tubewell
hand pump open well
(If hand pump or open well, quality of water Sweet
Saltish
- 21 Total number of latrines — —
No. of latrines located on ground floor
first floor 2nd floor top floor
Nature of floor of the latrines How many 1. —
pacca 2. broken
How often cleaned daily? Once, twice
How many have flush system?
How many are combined with bath room?
22. Drainage outside the house pacca, lachha,
Are the drains connected with the main drains?
drains? Yes, no

Are there any water troughs (*hounds*) ? Yes no

If so whether kachha pacca

Who cleans them ? Sweeper corporation lorry,
not cleaned

Specify if any stagnant water collects anywhere

23 Other nuisances Rats bugs bad smell

24 How many times a year is the house whitewashed? .

25 Is any shop attached with the house ? Yes no

If so nature of the business carried on --- ---

Cubic space occupied by the shop --- --

Is the house owner himself the business man ?

Yes no

If not rent paid by the shopkeeper -- --

26 General condition of the house -- --

For each Family

House No. Family No. ---

1 Family Owner, Tenant

2 (a) Religion and nationality Hindu Muslim Sikh,
Christian Parsee Indian Christian Anglo Indian,
European Others (specify)

(b) Domicile (Province or State) --

3 Since when living there - --

4 Occupation of Earners and distance of places of their
work from the house --

(a)

(b)

(c)

- 5 Numbers actually living (exclude servants living outside)—

	Male	Females	Total
Adults	—		
Children (5-15 years)	—		
Babies (below 5 years)	—	—	
Grand total	—	—	

- | | Males | Females | Total |
|---------------------------------------------------------------------------------------------------------------|-----------|--------------|-------|
| 6 Literates (Above 5 years) | | | |
| 7 Married | — | | |
| Widowed | | | |
| Unmarried | | | |
| 8 No of living rooms | — | | |
| (a) how many are completely dark? | | | |
| (b) how many are well ventilated? | | | |
| ($\frac{1}{2}$ th of the base area of the room opening into external air) | | | |
| 9 No of separate kitchens | | Nil one two | |
| Kitchens having chimneys | | Nil one two | |
| Bath rooms | | Nil one, two | |
| Godowns | — — — — — | Nil one, two | |
| Garage | — — — — — | Nil one two | |
| Latrines | | Nil one, two | |
| 10 If no drinking water arrangement inside the house state distance of the source of supply of water in yards | | | |
| 11 Lighting arrangement Electricity kerosene & rapeseed oil | | | |
| 12 Fuel used firewood, charcoal, soft coke, dung & saw dust electricity | | | |
| 13 Where does the family sleep in summer? top floor | | | |

inside the room, verandah, outside the house, open space

- 14 No of separate servants' quarters (if any) -----
 Total cubic space (in cubic feet)
 No of persons living
- 15 No of domestic animals, if any, cows,
 buffaloes goats sheep
 horses dogs poultry
- 16 Is there any separate accommodation for domestic animals? ..Yes, no.
- 17 Approximate monthly income of the family
- 18 If tenant monthly rent paid -

Date

II—INTERPRETATION OF DATA

Statistical methods are liable to misuse either deliberately or unintentionally.

When the methods are not correctly applied statistics are not to be blamed for their unreliable characters, or for wrong interpretation, *but* the persons who are handling them without having good knowledge of the science of statistics. Only qualified persons in statistics should take up the analysis and interpretation of the statistical data. Interpretation means drawing inferences from an analytical study of the collected data.

1 In any inductive reasoning statistical methods play a prominent part. Before giving any judgment and in drawing conclusions and inferences care must be taken to see that the data are sufficient, homogeneous and comparable, and the effects of all the other disturbing factors have been fully taken into account.

Statistical data are often interpreted wrongly due to false generalisation. For example, statistics with regard to the increase in quantity and value of imported goods are quoted to justify the conclusion that people are in a prosperous

This conclusion would be valid only when the consumption of indigenous goods is not decreasing to a greater extent. Increase in the consumption of articles of luxury would show general prosperity only when majority of the people get benefit.

Sometimes mistakes are made in wrongly interpreting averages, index numbers, coefficient of correlation and co-efficient of association

In short, statistics should be carefully collected, unbiased errors, statistical methods should be skilfully and intelligently applied, by statisticians, and tested according to various tests of significance, in order to have reliable analysis and interpretation of data

III—MATHEMATICAL PROOFS OF THEOREMS ON PROBABILITY AND MOMENTS

In chapter XI the statements of the Addition and Multiplication theorems of Probability were given. Here we give simple proofs for them

Let the main event E , fall in n groups of subsidiary events of which only one can happen in a single trial but each of which any one will bring the event E . Let t denote the number of equally likely cases. Of the possible cases f be in favour of the event. The favourable group of cases may be divided into n subgroups of which f_1 are favourable for the happening of the subsidiary event E_1 , f_2 in favour of E_2 , f_n in favour of E_n . Therefore the probability p of the whole event E

$$\begin{aligned} p &= \frac{f}{t} = \frac{f_1 + f_2 + f_3 + \dots + f_n}{t} = \frac{f_1}{t} + \frac{f_2}{t} + \dots + \frac{f_n}{t} \\ &= p_1 + p_2 + p_3 + \dots + p_n \end{aligned}$$

which proves the *Addition Theorem*.

Multiplication Theorem.—Let the number of possible cases, for the whole event E be t , for E_1 be t_1 , — for E_n be t_n

Each of the t_1 possible cases corresponding to the event E_1 may occur simultaneously with each of the t_2 cases

corresponding to the event E_2 . Thus there will be altogether $t_1 \times t_2$ cases falling on the events E_1 and E_2 at the same time.

Continuing the reasoning, the total number of equally likely cases resulting from the simultaneous occurrence of the events E_1, E_2, \dots will be $t_1 \times t_2 \times t_3 \times \dots \times t_n$.

If f denote the favourable cases for the whole event E , f_1, f_2, \dots, f_n the favourable cases for E_1, E_2, \dots then following the above reasoning the probability for the whole

$$\begin{aligned} \text{event } E \text{ is } p &= \frac{f}{t} = \frac{f_1 \times f_2 \times f_3 \times \dots \times f_n}{t_1 \times t_2 \times t_3 \times \dots \times t_n} \\ &= \frac{f_1}{t_1} \times \frac{f_2}{t_2} \times \frac{f_3}{t_3} \times \dots \times \frac{f_n}{t_n} \\ &= p_1 \times p_2 \times p_3 \times \dots \times p_n \end{aligned}$$

which proves the theorem.

The theorem holds for dependent as well as Independent events.

To determine the mean and variance for the binomial $(q+p)^n$

From the expansion of $(q+p)^n$ the frequencies corresponding to the number of successes 0, 1, 2, ..., n

are the terms, $q^n, nq^{n-1}p, \frac{n(n-1)}{2} q^{n-2}p^2, \dots, p^n$.

Taking 0 as the Provisional mean for the series 0, 1, 2, ..., n of successes, the deviations (D) will be $D=0, 1, 2, \dots, n$

$$\text{and } f = q^n, nq^{n-1}p, \dots, p^n.$$

$$\Sigma D = nq^{n-1}p + n(n-1)q^{n-2}p^2 + \dots + np^n.$$

$$= np[q^{n-1} + (n-1)q^{n-2}p + \dots + p^{n-1}]$$

$$= np[q+p]^{n-1} = np \text{ since } q+p=1.$$

$$\text{The Arithmetic mean} = 0 + \frac{\Sigma f D}{\Sigma f}$$

$$= \frac{np}{1} = np \text{ since sum of frequencies is } (q+p)^n = 1.$$

To find the standard deviation and variance

$$\Sigma f = 1$$

let us find the value of $\frac{\sum f D^2}{\sum f}$

$$\begin{aligned}\sum f D^2 &= 0 + n q^{n-1} p + 2n(n-1) q^{n-2} p^2 + n^2 p^3 \\ &= np \left\{ q^{n-1} + 2(n-1) q^{n-2} p + \frac{3(n-1)(n-2)}{2} q^{n-3} p^2 \right. \\ &\quad \left. + n p^{n-1} \right\} \\ np \left\{ \left\{ q^{n-1} + (n-1) q^{n-2} p + \frac{(n-1)(n-2)}{2} q^{n-3} p^2 + p^{n-1} \right\} \right. \\ &\quad \left. + \left\{ (n-1) q^{n-2} p + \frac{2(n-1)(n-2)}{2} q^{n-3} p^2 + \dots \right. \right. \\ &\quad \left. \left. + (n-1) p^{n-1} \right\} \right\} \\ &= np \{ (q+p)^{n-1} + (n-1)p \{ q^{n-2} + (n-2)q^{n-3}p \} + p^{n-1} \} \\ &= np \{ 1 + (n-1)p(q+p)^{n-2} \} \\ &= np \{ 1 + p(n-1) \} = np + n^2 p^2 - np^2 \\ \text{Variance is given by the formula} \\ \frac{\sum f D^2}{\sum f} - \left(\frac{\sum f D}{\sum f} \right)^2 \\ &= np + n^2 p^2 - np^2 - (np)^2 \\ &= np(1-p) = npq\end{aligned}$$

and $\sigma = \sqrt{npq}$

Moments In chapter X, the moments about the mean are given in terms of the moments about any arbitrary origin. Here we shall establish these relations.

If A denote the provisional mean, the moments about any mean are defined by

$$V_r = \frac{1}{n} \sum (x-A)^r = \frac{1}{n} \sum D^r$$

If M denote the arithmetic mean, the moments about the

Mean are given by $V_r = \frac{1}{n} \sum (x-M)^r = \frac{1}{n} \sum d^r$.

$V_1 = \frac{1}{n} \sum f D$ where n stands for the sum of the frequencies $= \sum f$

It is known that

$$\text{Arith. Mean} = A + \frac{\sum f D}{n}$$

$$\therefore V_1 = M - A.$$

$$\mu_1 = \frac{1}{n} \sum f d = \frac{1}{n} \left\{ f_1(x_1 - M) + f_2(x_2 - M) + \dots + f_n(x_n - M) \right\}$$

$$= \frac{1}{n} \left\{ \sum f x - nM \right\} = 0, \text{ since}$$

$$M = \frac{\sum f x}{n}.$$

Let us establish in general μ_r 's in terms of V_r

$$D = x - A = (x - M) + (M - A) \\ = d + V_1.$$

$$\begin{aligned} \mu_r &= \frac{\sum f d^r}{n} = \frac{1}{n} \left[\sum f (D - V_1)^r \right] \\ &= \frac{1}{n} \left\{ \sum f (D^r - r D^{r-1} V_1 + \frac{r(r-1)}{2} D^{r-2} V_1^2 \right. \\ &\quad \left. - \frac{r(r-1)(r-2)}{3!} D^{r-3} V_1^3 + \dots + (-1)^r V_1^r \right\} \\ &= \frac{1}{n} \sum f D^r - r V_1 \frac{1}{n} \sum f D^{r-1} + \frac{r(r-1)}{2} \end{aligned}$$

$$V_1^2 \sum f D^{r-2} + \dots + (-1)^r V_1^r$$

$$= V_r - r V_1 V_{r-1} + \frac{r(r-1)}{2} V_1^2 V_{r-2} + (-1)^r V_1^r.$$

Putting $r=1, 2, 3, 4 \dots$ we express the moments about the mean in terms of the moments about the Provincial Mean.

IV.—Punjab University Question-Papers for Sta in 1946 Examination. (Attached).

CERTIFICATE IN STATISTICS (C St.) EXAM 1946
PAPER I AND M.A. ECONOMICS—PAPER V (b)
OPTION (ii)

STATISTICS

Time allowed Three hours

Maximum Marks . 100

Only five questions are to be attempted atleast two of which must be from each of Sections A and B

All questions carry equal marks

SECTION A

1 Suggest a plan for social economic survey of Lahore. Give details

2. Write an essay on the analysis of time series.

3. You are asked to compile a working class cost of living Index for Lahore Suggest a plan Give details

4 How is a population census organised in India? State the methods of obtaining inter-censal year estimates of the population

5 Write notes on the statistical concept of —

(a) Frequency distribution.

(b) Standard Deviation.

(c) Correlation

SECTION B

6 The following table shows the age distribution of married females according to sample census of 1941 in the Baroda State —

Age	No of married females
0 and above	3
5 " "	31
10 " "	410
15 " "	1809
20 " "	2446
25 " "	2223
30 " "	1723
35 " "	1292
40 " "	963
45 " "	762
50 " "	531
55 " "	317
60 " "	156
65 " "	59
70 " "	37
<hr/> All ages	<hr/> 12762

Draw a graph showing the number of married females younger than any given age. Hence or otherwise calculate the median age of married females and also the two quartiles, upper and lower.

Ans 28.783, 21.916, 38.585

7. Fit a straight line to the following data showing the yield of wheat in bushels per acre from the same plot during 20 years

1855	1856	1857	1858	1859	1860	1861
29.62	32.38	43.75	37.56	30.00	32.62	33.75
1862	1863	1864	1865	1866	1867	1868
43.44	55.56	51.06	44.06	32.50	29.13	47.81
1869	1870	1871	1872	1873	1874	
39.00	45.50	34.41	40.69	35.81	38.19	

Ans $36.375 + 235x$ (1854 origin)

8 The correlation Table given below shows for each of 78 towns (1) measures of the amount of over crowding present in a given year and (2) the infant mortality rate in the same year Calculate the coefficient of correlation between over crowding and infant mortality rate

Infant Mortality Rate	Percentage of population in private families living more than two persons per room						Total
	1.5-4.5	4.5-7.5	7.5-10.5	10.5-13.5	13.5-16.5	16.5-19.5	
36	—	5					5
46		9	1				10
56		10	4	1		1	16
66		4	7	5	2		18
76		2	5	4	1	1	13
86			2	2	2	1	7
96			1	2	2	1	7
106-116			1	—	1		2
Total	30	21	14	8	2	3	78

Ans '65 (approx).

9 Use the method of interpolation to obtain the value of y for $x=7.5$ from the following data

x	4	5	6	7	8	9	10
y	941	948	967	1004	1065	1156	1283

Ans. 1031.125.

M A (MATHEMATICS,—PAPERS IV, V, VI (OPTION F)) STATISTICS

Time allowed Three hours

Maximum Marks 100

N.B. —Not more than *nine* questions should be attempted. All questions carry equal marks, and *six* carry full marks. Greater credit will be given to complete questions correctly answered than to a proportionate number of fragmentary answers.

1 Assuming the Gregory Newton Formula of Interpolation, obtain the expressions for the first two differential coefficients of the function $f(x)$ for the value ' a ' of its argument, in terms of the differences.

Given the following data, compute the first two differential coefficients of the function ' y ' corresponding to the argument $x=11$

x	y
2	1,08,243
5	— 1,21,551
9	1,41,158
13	— 1,63,047
15	— 1,74,901

2 Obtain the expression for the Euler MacLaurin Formula for the summation of series

Apply the formula to sum the following series to infinity

$$\frac{1}{101^2} + \frac{1}{103^2} + \frac{1}{105^2} + \frac{1}{107^2} + \dots$$

3 Explain the method of forming the Normal Equations

for a set of variables in which the number of equations given is greater than the number of unknowns

Discuss the method of solving these equations by the method of determinants.

4 Define 'probability' and explain the terms, 'Mutually Exclusive', and 'Mutually Independent' as applied to events.

Given n independent events with respective probabilities of occurrence p_1, p_2, \dots, p_n , prove that one of the probability of at least one of the events happening is

$$\sum p_i - \sum p_i p_j + \sum p_i p_j p_k - \dots$$

This sides of a rectangle are chosen at random, each being less than a given length ' a ', all such lengths being equally likely Find the chance that the diagonal is less than ' a '.

5 The following table gives the monthly average production of boots and shoes in U S A Fit a curve of the form $a + bx + cx^2$ to this data

Years	1923	1924	1925	1926	1927	1928	1929	1930	1931	1932	1933
Average production (in millions)	29.3	26.1	27.0	27.5	28.6	29.2	30.1	25.4	26.4	26.1	29.6

6 Assuming the conditions of simple Sampling, how do you test the significance of the difference between the 'values of Arithmetic Mean' and 'Standard Deviation' obtained from a sample with those of the total population.

In studying the problem of density of population per house, from a population of 1,00,000 houses, a random sample of 1,000 was selected and the following results were obtained

NUMBER OF PERSONS PER HOUSE

	1	2	3	4	5	6	7	8	9	10
Whole population 100	56	216	243	199	124	75	44	22	11	6
Sample	54	225	237	193	121	79	41	27	10	8

Compute the values of Arithmetic Mean, and Standard Deviation of the number of persons per house, both for the whole population as well as for the sample. Are the values of Estimates of these two from the sample, significantly different from those of the population?

7. The number of males in each of 106 eight pig litters was found and they are given by the following frequency distribution —

Number of males per litter	0	1	2	3	4	5	6	7	8	Total
Frequency	0	5	9	22	25	26	14	4	1	106

Assuming that the probability of an animal being male or female is even (i.e. $p=q=\frac{1}{2}$), and the frequency distribution follows the Binomial law, calculate the expected frequencies of the nine classes. Find also the values of χ^2 to test the goodness of fit.

8. If x_1 is the dependent variable, and x_2 and x_3 the two independent variables, obtain the regression equation of x_1 in terms of x_2 and x_3 .

Give the following values of Arithmetic Mean, Standard Deviation and Co-efficient of Correlation of 740 sets of values find the regression equation of x_1 in terms of x_2 and x_3

$\bar{x}_1 = 28.02$	$\sigma_1 = 4.42$	$r_{12} = 0.80$
$\bar{x}_2 = 4.91$	$\sigma_2 = 1.10$	$r_{13} = -0.40$
$\bar{x}_3 = 594$	$\sigma_3 = .85$	$r_{23} = -0.56$

9. x and y are two correlated variables, measured from their respective arithmetic means. If the standard deviation of each is unity and the coefficient of correlation between the two is r , for what values of θ are the two variables $X = x \cos \theta + y \sin \theta$, $Y = x \sin \theta + y \cos \theta$, uncorrelated? What are the values of the standard deviations of the variables X and Y ?

10. The following table gives the results of experiment on four varieties of a crop in 5 blocks of plots:—

		Block				
		1	2	3	4	5
Variety	A	32	34	33	35	37
	B	34	33	36	37	35
	C	31	34	35	32	36
	D	29	26	30	28	29

Prepare the table of analysis of variance to test the significance of difference between the yields of the four varieties

11 Write short notes on *any four* of the following —

(a) Poisson's Distribution. (b) Lexian Ratio (c) ϕ -efficient of contingency. (d) Sheppard's Corrections (e) Method of Moments (f) Fourier's analysis and its application to time series

B COM 1946

STATISTICS

Time allowed three hours.

Maximum Marks 100.

Answer five questions only of which at least two must be from Group A and two from Group B All questions carry equal marks

GROUP A

1 Define Statistics and point out the main difficulties that a statistician has to face as compared with a physicist or chemist

How will you classify a given commercial data ?

2. It is required to estimate the total consumption of food grains in the Punjab for enforcing a scheme of food rationing. What statistical data should be collected for this purpose and how ?

3 How would you use the method of random sampling in making an economic survey of villages in the Punjab ?

4 What is the importance of the census of and that of production ?

How will you organise those censuses in your Province ?

5 Write notes on three of the following giving examples

Probability Mode Tabulation Moving A
Index numbers Regression

GROUP B

6 The following table gives five yearly percentage in Bombay Presidency under cotton and under food. Calculate the coefficient of correlation between the area under cotton and the area under food crops —

<i>Year</i>	<i>Percentage area under cotton</i>	<i>Percentage under food</i>
1908	38.5	52.7
1909	38.5	52.3
1910	38.8	53.0
1911	37.8	53.5
1912	39.1	52.5
1913	39.5	52.3
1914	38.0	54.9
1915	38.4	54.3
1916	38.8	53.2
1917	39.2	52.6

Ans —

7 The following table gives the population of Lucknow the time of the previous censuses —

1891	2,64,953
1901	2,56,239
1911	2,32,332
1921	2,17,167
1931	2,51,097

Estimates the population of Lucknow for 1916

Ans 221520

8. The following table gives the detail of monthly expenditure of three families —

<i>Items of Expenditure</i>	<i>Family A</i>	<i>Family B</i>	<i>Family C</i>
	Rs a	Rs a	Rs a
Food	12 0	30 0	90 0
Clothing	2 0	7 0	35 0
House-rent	2 0	8 0	40 0
Education	1 8	3 0	12 0
Medical	1 0	5 0	40 0
Conventional necessity	0 8	3 0	60 0
Miscellaneous	1 0	4 0	23 0

Represent the above figures by a suitable diagram which family is spending the money most wisely ?

9 (a) Following are the group index numbers, and the group weights of an average working class family's budget. Construct the cost of living index number by signing the given weights

Group	Index number for January 1943	Weight
Food	152	48
Fuel and lighting	110	6
Clothing	130	8
House-rent	100	12
Miscellaneous	90	15

(b) Calculate the variance for the given index number in (a). Ans 129.73, 49

B A HONS.

ECONOMICS PAPER III OPTION (III) STATISTICS

Time allowed : three hours

Maximum Marks 60.

Attempt five questions, atleast two being from C and two from Group B. All questions carry equal marks.

GROUP A.

1. 'The application of statistical methods is extensive. But their application in economic and social life man to day most intimately' (Dr. Sir Manabhar Lal).

Elucidate with illustrations the above statement on utility of statistical methods in the present day and social conditions

2. What is the importance of graphic charts business statistics? What are the various types of diagrams and graphs commonly used? What precautions should be taken in using pictorial or popular presentations

3. What do you understand by skewness? What the various methods of its measurement? Illustrate answer by suitable example.

4 What is the use of a cost of living index number ? How is it constructed ? What are its drawbacks ?

5 Write explanatory notes on any three of the following —

(i) Sampling

(ii) Statistical errors

(iii) Lorenz curve

(iv) Seasonal fluctuations

(v) Chain base index numbers

GROUP B

6. Present the data given in the following paragraph in the form of a table, so as to bring out clearly all the facts, indicating the source and bearing a suitable title

According to the Census of Manufacturers Report 1945 the John Smith Manufacturing Company employed 400 non-union and 1250 union employees in 1941. Of these 220 were females of which 140 were non-union. In 1942, the number of union employees increased to 1475 of which 1300 were males. Of the 250 non-union employees 200 were males. In 1943, 1700 employees were union members and 40 were non union. Of all the employees in 1943, 250 were females of which 240 were union members. In 1944, the total number of employees was 2000 of which one per cent. were non union. Of all the employees in 1944, 300 were females of which only 5 were non union

7. "Capital" Index of Indian cotton consumption in January 1944 to May 1945 is given below :—

1944	Index	1944	Index
January	157.5	October	154.2
February	156.1	November	165.9
March	158.9	December	162.6
April	148.1	1945	
May	153.3	January	163.1
June	161.7	February	148.1
July	157.5	March	174.3
August	160.3	April	158.9
September	161.2	May	165.9

Represent the above data in the form of a ' ' and indicate the trend based on three-monthly moving average

8. Compute the Standard Deviation and the coefficient of variation from the following data of monthly wages paid in a cotton factory —

Wage grades Rs	Number of employees
15—25	7
25—35	102
35—45	111
45—55	360
55—65	159
65—75	33
75—85	13
85—95	11
95—105	0
105—115	4
Total	600

9 From the following record of marks obtained in Economics by a batch of 55 students, indicate the value of the median and the modal marks

12,	17,	18,	20,	20,	24,	25,	28,	30,	30,	33,	33,
33,	33,	33	33,	34,	34	35,	35,	36,	37,	38,	40,
40,	40,	42,	44,	45,	45,	48,	48,	48,	48,	48	48,
49	50,	50,	50	51,	52,	53	54,	55,	56,	58,	58,
	59,	59	61,	62,	64,	65,	68				

CERTIFICATE IN STATISTICS 1946

PAPER II.

Time allowed three hours

Maximum Marks 100

Attempt five questions only at least two from each Group.
All questions are of equal value

GROUP A

1 Write a note explaining the various uses of Fisher's Z statistics

Or

't' tests

2 Explain the importance of 'replication', 'randomisation' and 'local control' in agricultural field experiments, and mention some of the devices by which local control is achieved

3 Write a short essay on the use of 'Control charts' or on Official statistics in India

4. It is required to determine the percentage of literates in your district Give any sample survey scheme to obtain the desired information

5 Define 'multiple' and partial correlation, and explain with illustrations, the use of these statistical concepts.

GROUP B

6 Find by interpolation the missing value in the following table —

<i>Degrees of freedom</i>	<i>One per cent value of F</i>
3	5.841
4	4.60†
5	4.032
6	.
7	3.499
8	3.355
9	3.250

7 The following table gives the frequency distribution of expenditure on food per family per month among working class families in two localities. Find the mean and standard deviation at both places, and test whether there is any real difference in the expenditure on food at these two places.

<i>Expenditure in Rs per month</i>	<i>Number of Families</i>	
	<i>Place A</i>	<i>Place B</i>
3—6	28	39
6—9	292	284
9—12	389	401
12—15	212	202
15—18	59	48
18—21	18	21
21—24	2	5

8. Calculate the first four moments for the frequency distribution —

x	89	86	74	65	64	63	66	67	72	79
f	92	91	84	75	73	72	71	75	78	84

9 From the following table showing the number of plants having certain characters, test the hypothesis that the flower colour is independent of flatness of leaf

	<i>Flat Leaves</i>	<i>Curled Service</i>	<i>Total</i>
White flowers	99	36	135
Red flowers	20	5	25
Total	119	41	160

You may use the following table giving the value of ψ^2 (chi-square) for one degree of freedom, for different values of P.

P	99	'95	'90	'50	'10	'05
ψ^2	000157	'00393	0158	'455	2.706	3.841
P	01					
ψ^2	6.635					

10. Set up a table of analysis of variance for :—

<i>Plots</i>	<i>Varieties</i>			
	<i>a</i>	<i>b</i>	<i>c</i>	<i>d</i>
1	200	230	250	300
2	190	270	300	270
3	240	150	145	180

TABLES OF LOGARITHMS, ANTI-LOGARITHMS, SQUARES, SQUARE ROOTS AND RECIPROCAL

The logarithm of a number consists of (1) integral part known as characteristic (2) Decimal part, known as Mantissa

The table of Logarithms gives the Mantissas upto four places of decimals, for numbers of three digits, for ready reference of the students. To find the Mantissa of any given number, take the number approximately to three digits and the table will give the approximate value. Mantissa of a number will be the same irrespective of the position of the decimal point in it

If more accuracy is required in the results, then five figure tables or seven figure tables should be used

The characteristics are to be found as

(1) When the given number is greater than 1, the characteristic will be positive and equal to $n-1$, where n is the number of significant digits before the decimal point. The characteristic in 514.98 is 2 and $\log 514.98 = 2 + .7118 = 2.7118$ nearly

(2) When the given number is less than 1, the characteristic is negative and is greater by one than the number of zeros which follow the decimal point. The characteristic of 0.034 is 3 (negative) and is written as $\bar{3}$.

For Anti-logarithms the 'reverse' of (1) and (2) are to be utilised.

The number, from the Antilog table, whose log is 1.6928 is 49.32 .

Tables of Squares, etc., are for numbers up to 100. For higher calculations tables such as Barlow's Tables for squares, etc. which gives for integers up to 12500 may be consulted. Calculating Machines like Facit, Brunsviga can also be used for rapid and heavy calculations.

LOGARITHMS

$\log 1 = 0$, $\log 2 = 301$, $\log 3 = 4771$ $\log 4 = 6021$ $\log 5 = 699$
 $\log 6 = 7782$ $\log 7 = 8451$ $\log 8 = 9031$ $\log 9 = 9542$
